Timing is critically important  
for event data

# Why not discrete the time axis for event data?

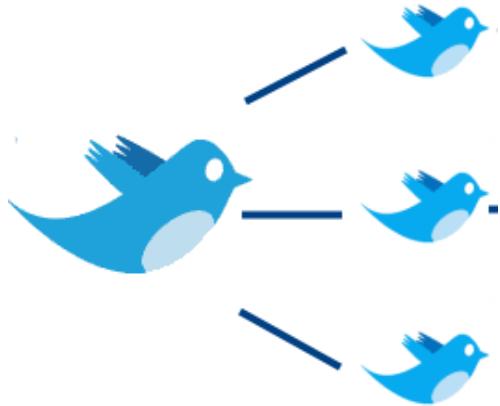

Discrete-time models artificially introduce epochs:

- How long is each epoch?
- How to aggregate events within epoch?
- What if no event within an epoch?
- Time is treated as index or conditioning variable, not easy to deal with time-related queries

# Dynamics are essential to many applications

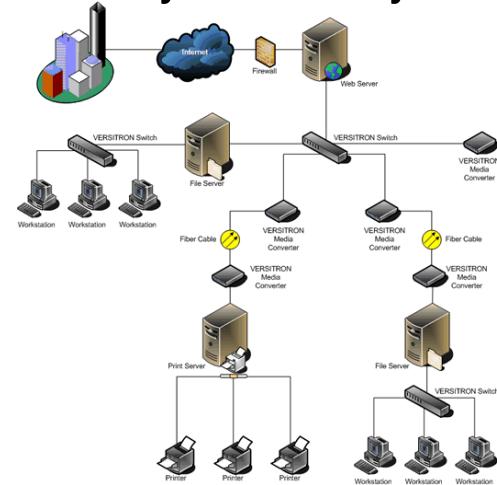

Information spread

Epidemiology

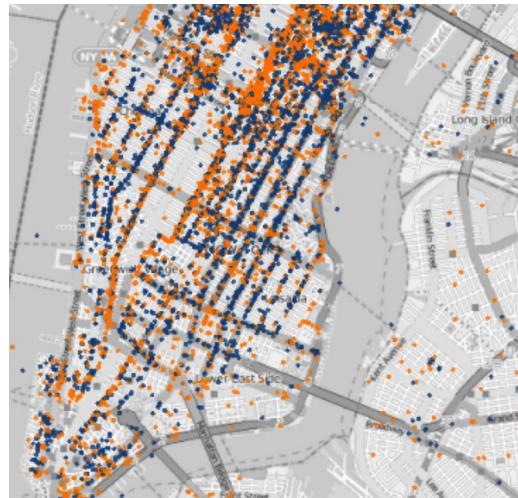

Cyber-security

Healthcare analytics

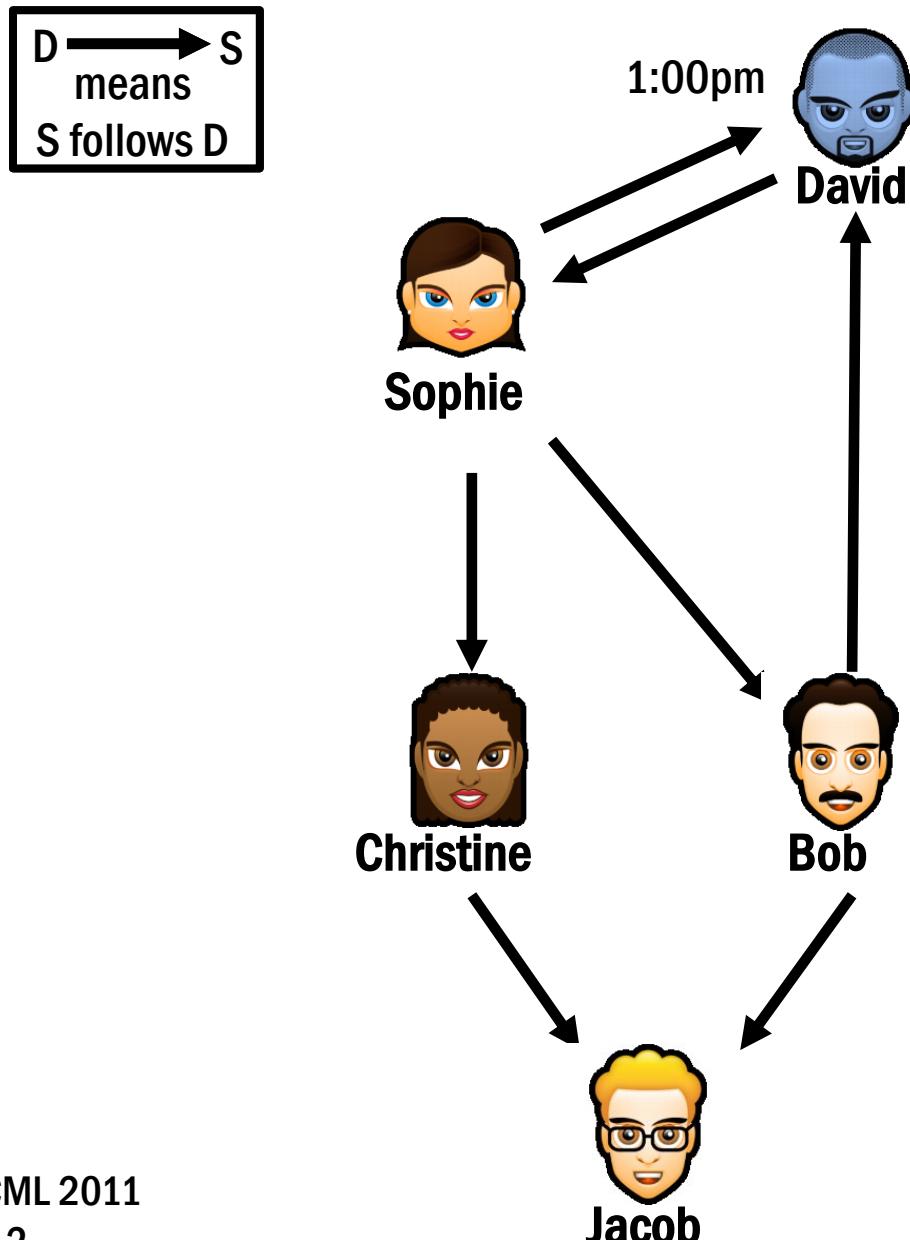

Smart city

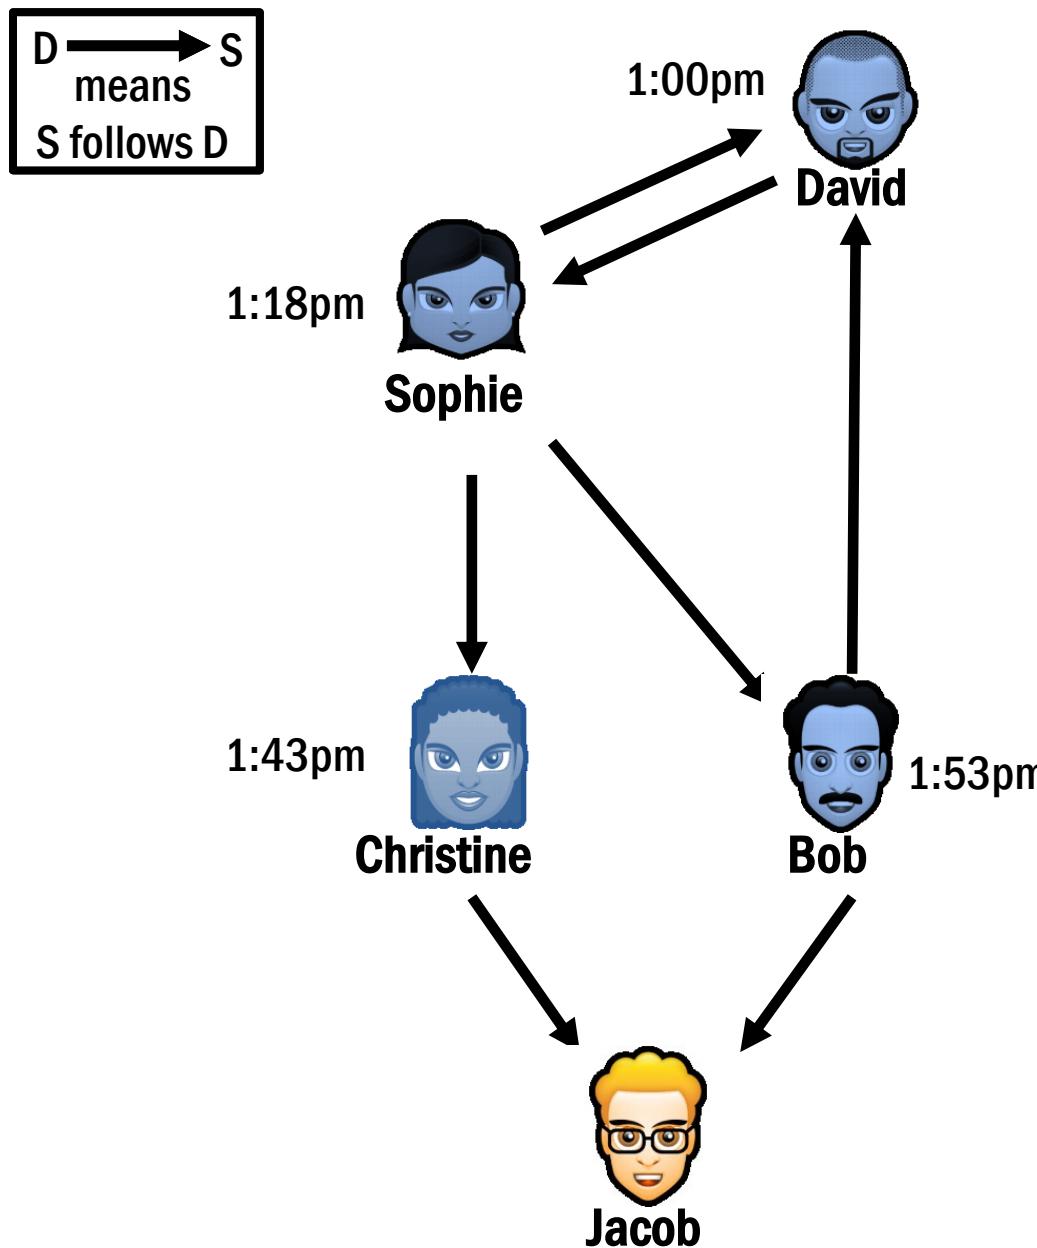

Wildlife conservation

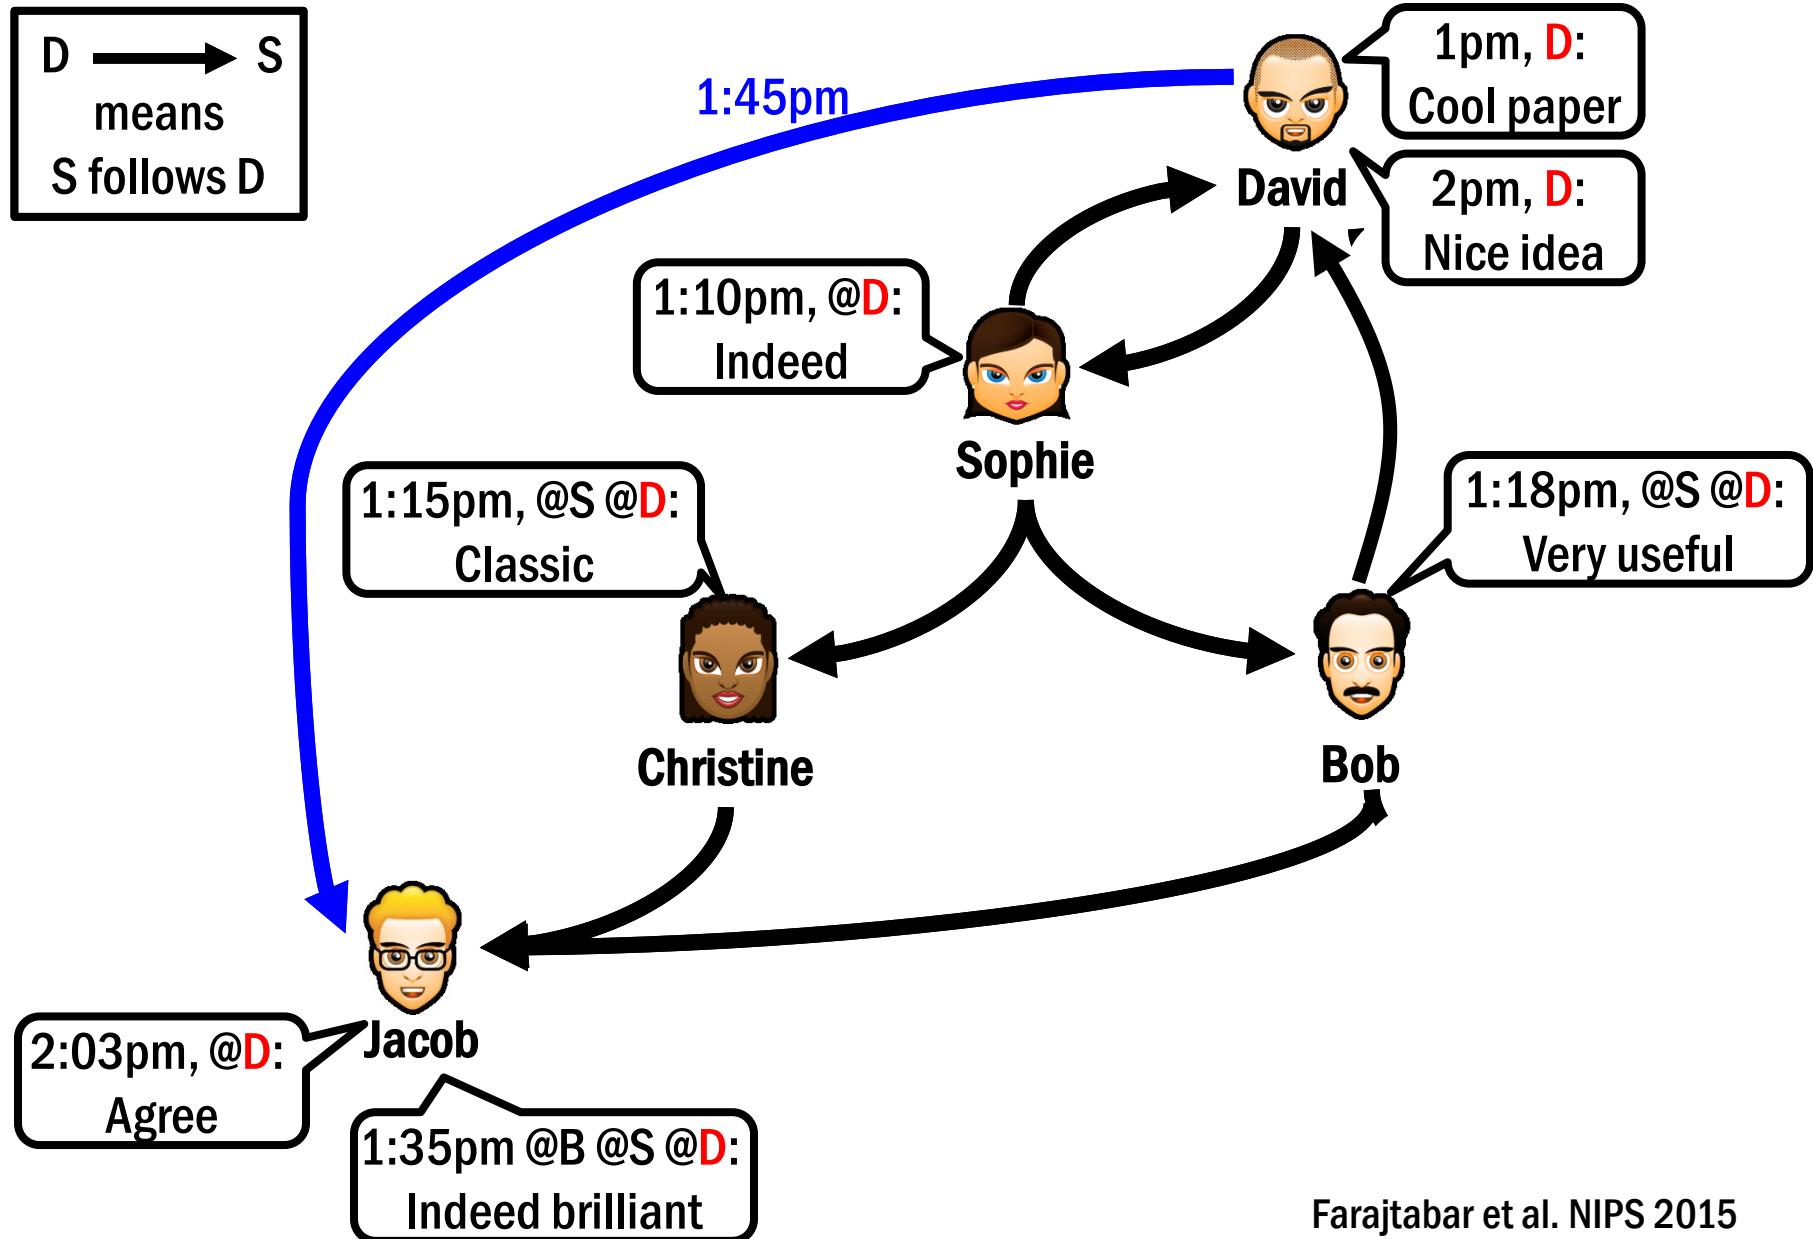

# Scenario I: Idea adoption/disease spread/viral marketing

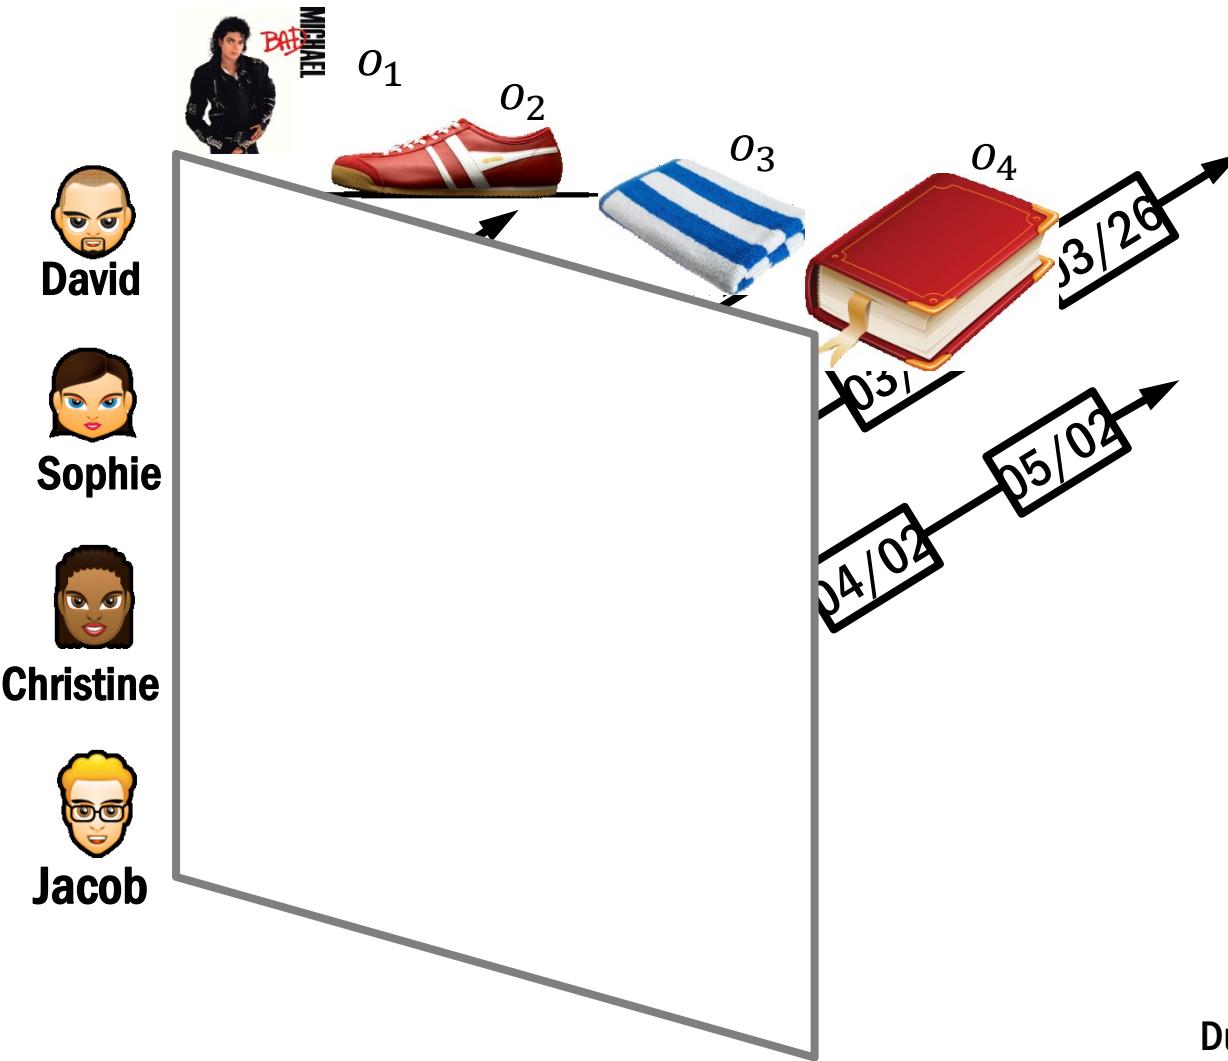

# Scenario I: Idea adoption/disease spread/viral marketing

# Scenario II: Information diffusion and network coevolution

# Scenario III: Collaborative dynamics

Du et al. NIPS 2015

# A unified framework

## Representation: introduce intensity

1. Intensity function
2. Basic building blocks
3. Superposition

## Modeling: incorporate domain specifics

1. Idea adoption
2. Network coevolution
3. Collaborative dynamics

## Learning : efficient algorithm

1. Sparse hidden diffusion networks
2. Low rank collaborative dynamics
3. Generic algorithm

## Inference: temporal queries

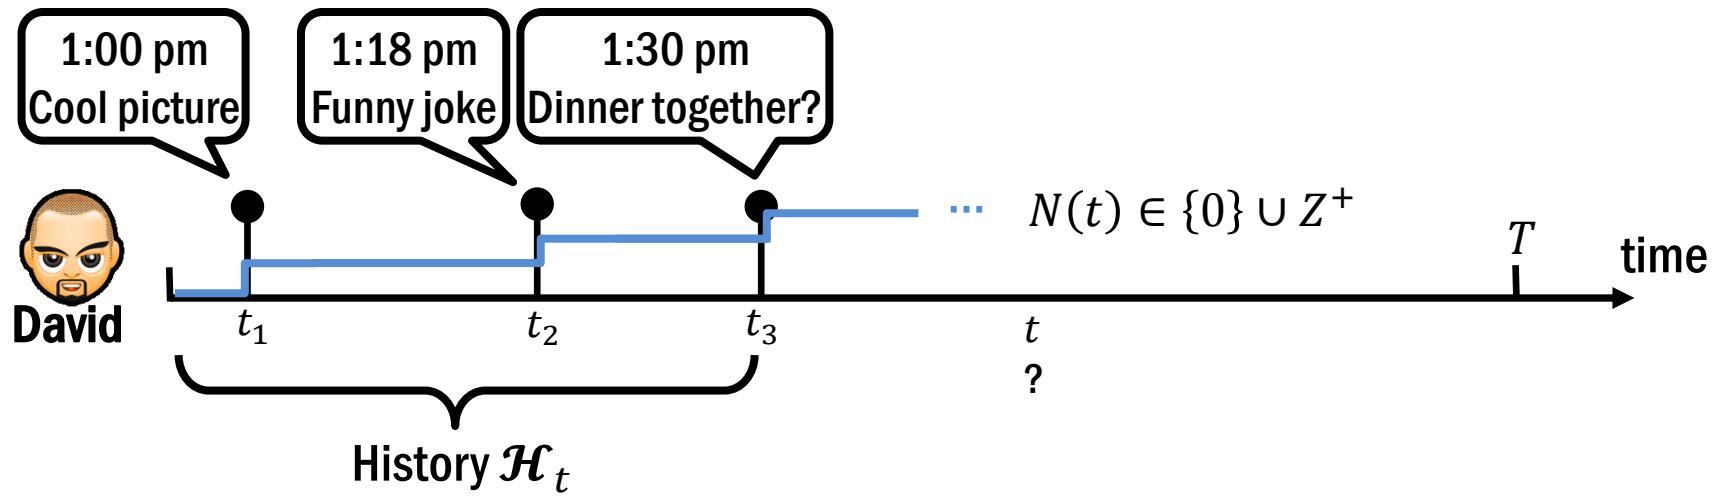

1. Time-sensitive recommendation
2. Scalable Influence estimation

# **Dynamic Processes over Information Networks**

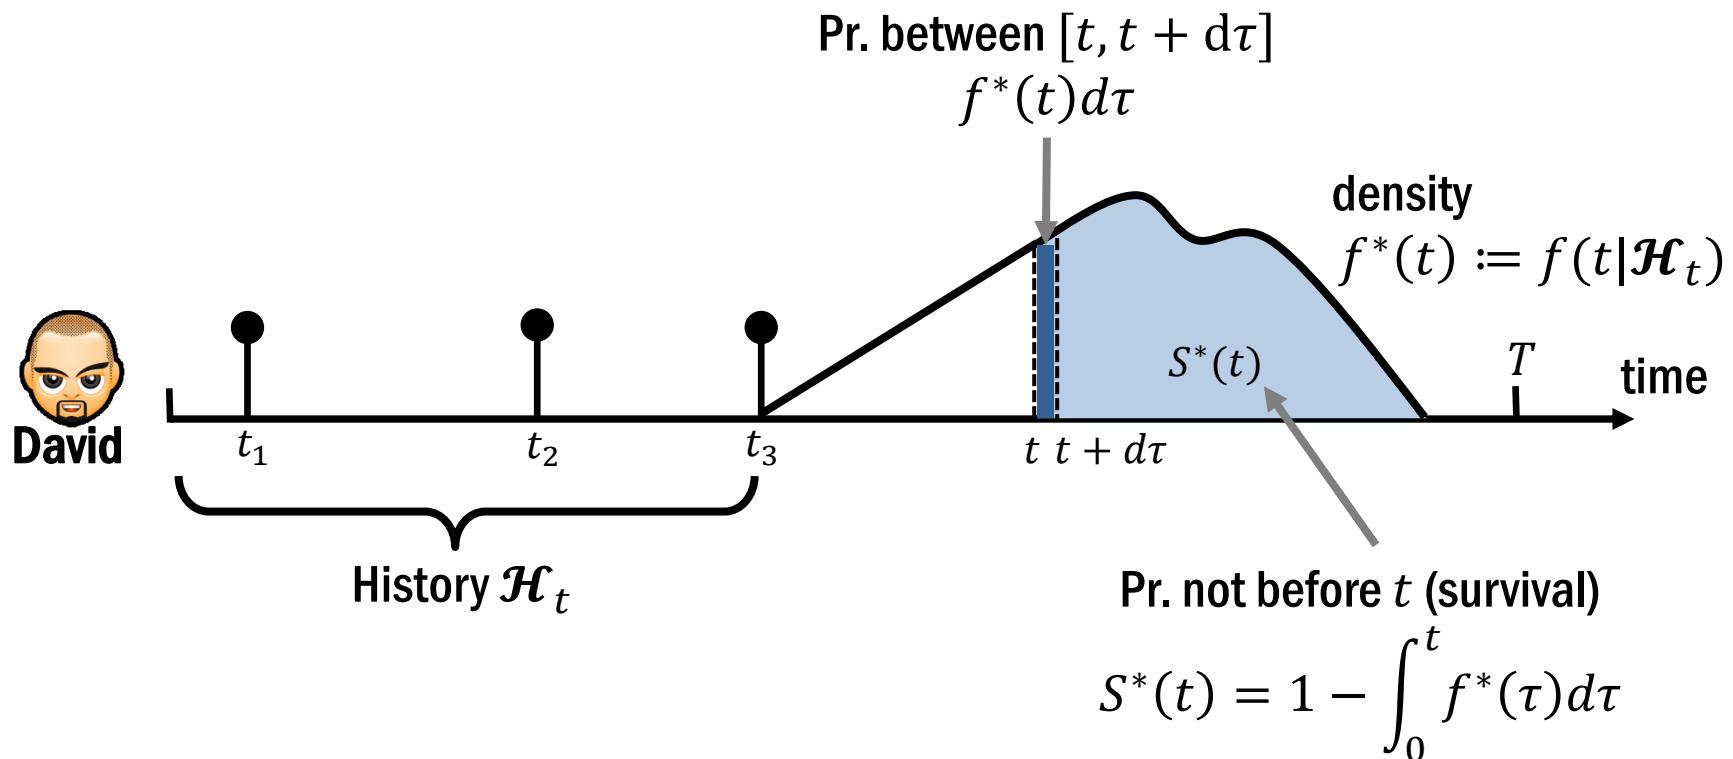

## **Representation, Modeling, Learning and Inference**

**Representation:**  
**Intensity Function**

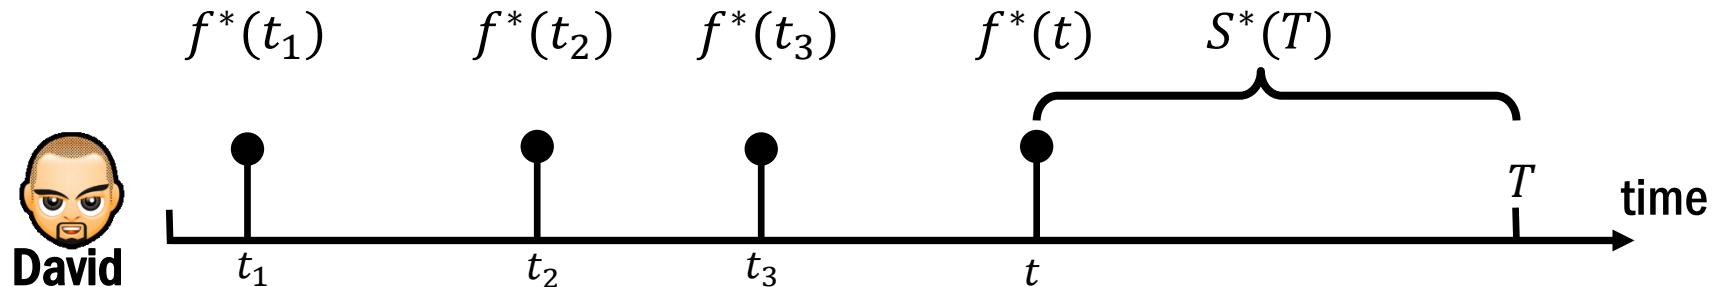

# History is a sequence of past events

# Model time as random variable

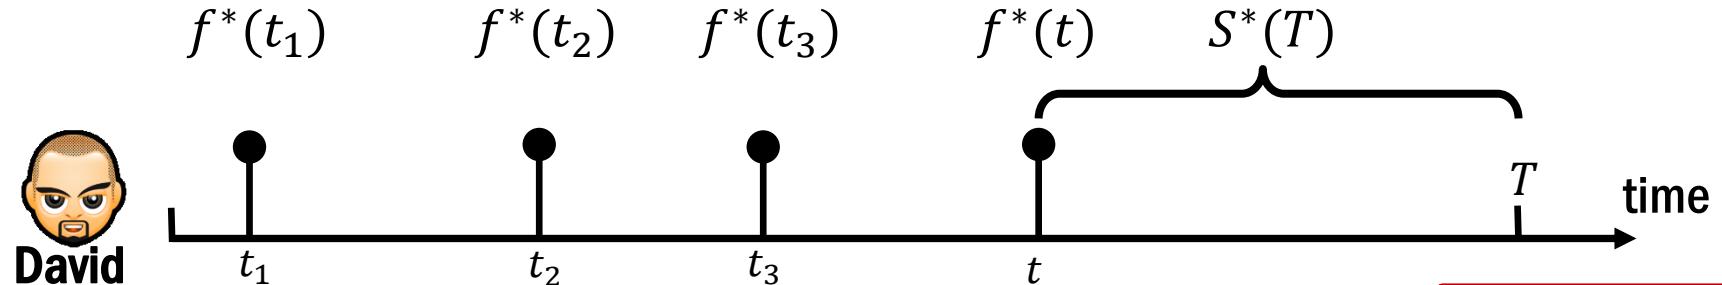

# Likelihood of timeline

Likelihood:

$f^*(t_1) \ f^*(t_2) \ f^*(t_3) \ f^*(t) \ S^*(T)$

# Problem of parametrizing density

Likelihood:

Not concave  
in w!

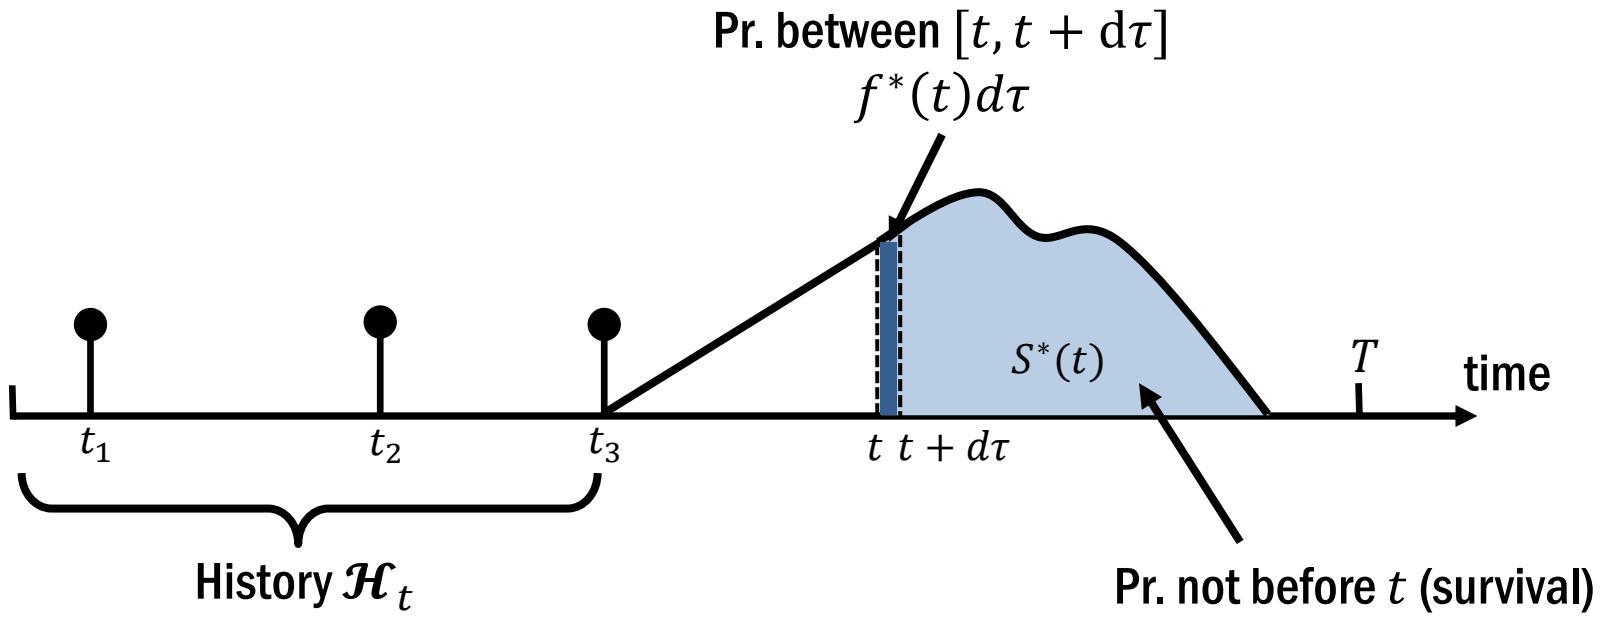

$$\frac{\exp\langle w, \psi^*(t_1) \rangle}{Z} \quad \frac{\exp\langle w, \psi^*(t_2) \rangle}{Z} \quad \frac{\exp\langle w, \psi^*(t_3) \rangle}{Z} \quad \frac{\exp\langle w, \psi^*(t) \rangle}{Z} \quad 1 - \int_0^T \frac{\exp\langle w, \psi^*(\tau) \rangle}{Z} d\tau$$

Arrows point from the terms  $\frac{\exp\langle w, \psi^*(t_1) \rangle}{Z}$ ,  $\frac{\exp\langle w, \psi^*(t_2) \rangle}{Z}$ ,  $\frac{\exp\langle w, \psi^*(t_3) \rangle}{Z}$ ,  $\frac{\exp\langle w, \psi^*(t) \rangle}{Z}$ , and  $1 - \int_0^T \frac{\exp\langle w, \psi^*(\tau) \rangle}{Z} d\tau$  to the corresponding  $f^*(t_i)$  and  $S^*(T)$  labels in the diagram above.

# Intensity function

David

Intensity: Pr. between  $[t, t + d\tau]$  but not before  $t$

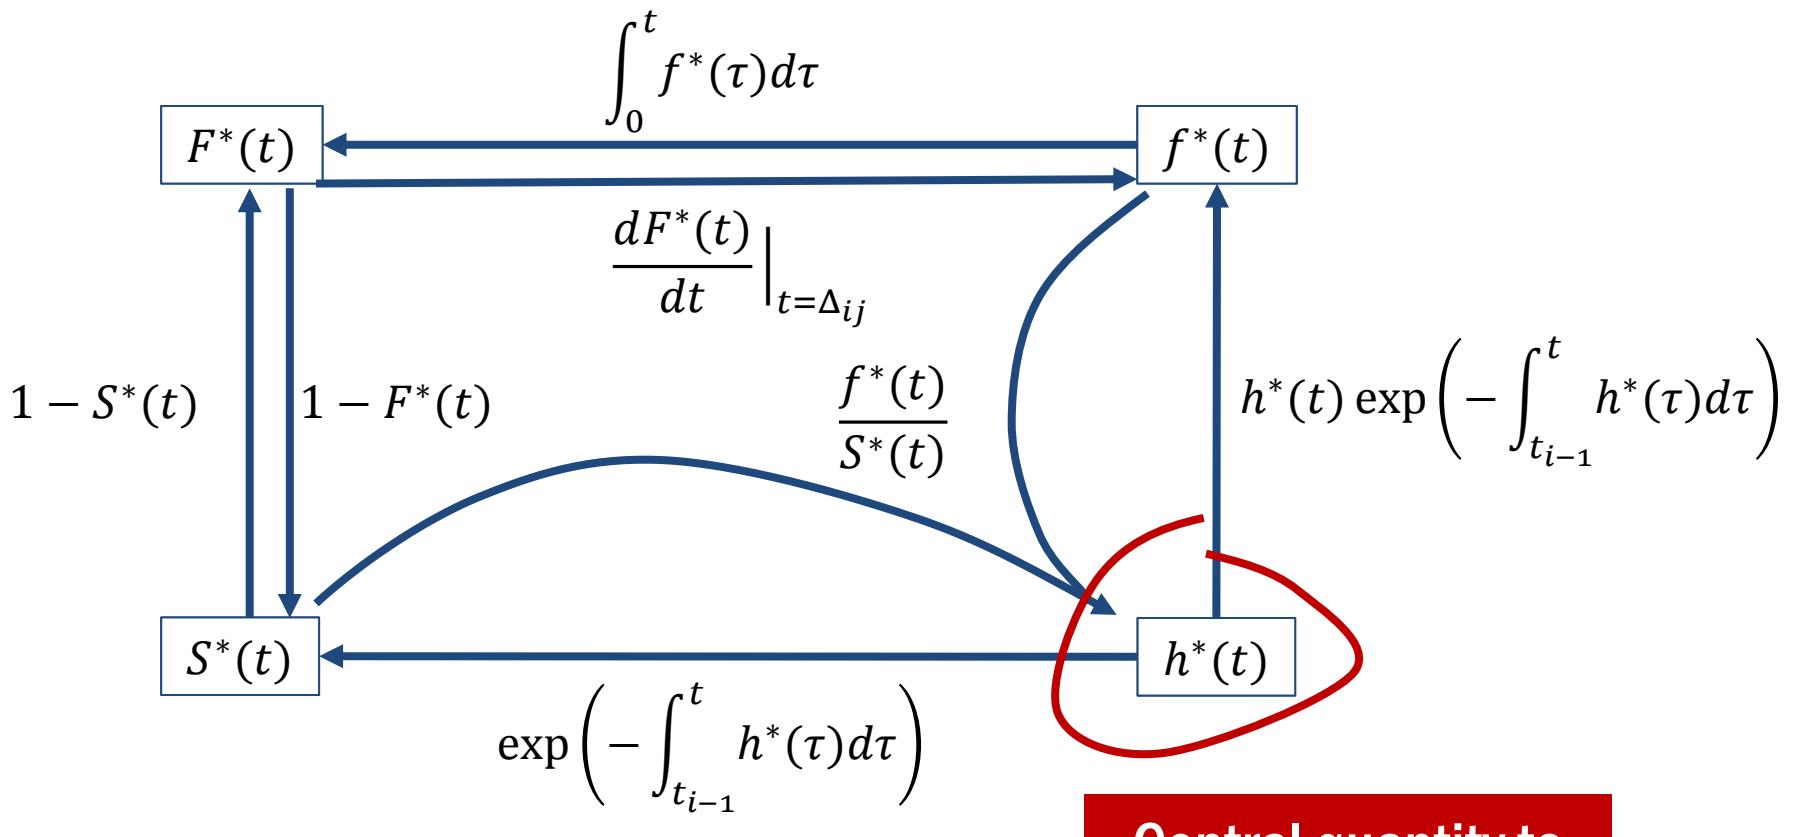

$$h^*(t)d\tau = \frac{f^*(t)d\tau}{S^*(t)} > 0$$

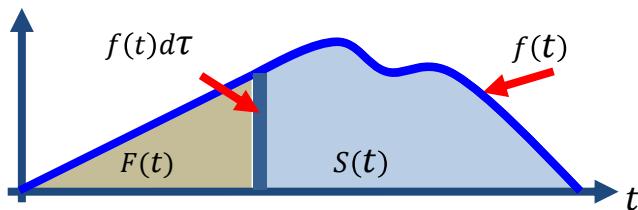

$$f^*(t) = h^*(t) S^*(t)$$

$$S^*(t) = \exp \left( - \int_{t_3}^t h^*(\tau) d\tau \right)$$

# Relation between $f^*$ , $F^*$ , $S^*$ , $h^*$

Central quantity to parameterize

# Advantage of parametrizing intensity

Log-likelihood

$$\sum_{i=1}^m \log \langle w, \phi^*(t_i) \rangle - \langle w, \Psi^*(T) \rangle$$

Concave in  
w!

Likelihood:

$$\begin{array}{ccccc} h^*(t_1) & h^*(t_2) & h^*(t_3) & h^*(t) & \exp\left(-\int_0^T h^*(\tau)d\tau\right) \\ \nearrow & \nearrow & \uparrow & \nearrow & \searrow \\ \langle w, \phi^*(t_1) \rangle & & \langle w, \phi^*(t_3) \rangle & & \exp\left(-\int_0^T \langle w, \phi^*(\tau) \rangle d\tau\right) \\ & \searrow & & \downarrow & \\ & \langle w, \phi^*(t_2) \rangle & & \langle w, \phi^*(t) \rangle & \end{array}$$

# **Dynamic Processes over Information Networks**

## **Representation, Modeling, Learning and Inference**

**Representation:**

# **Basic Building Blocks**

# Poisson process

Uniformly random occurrence.

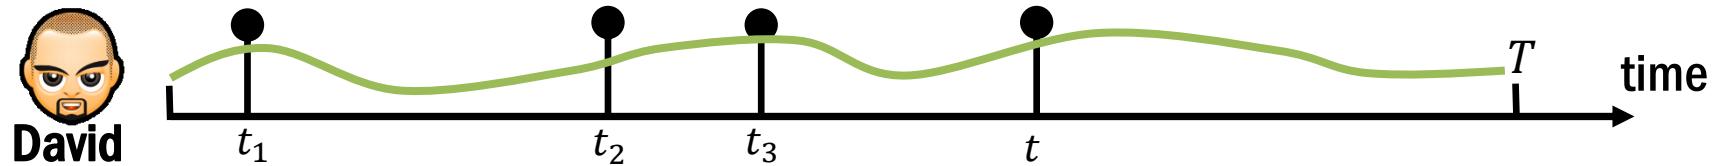

Time interval follows exponential distribution

$$h^*(t) = \mu$$

# Inhomogeneous Poisson process

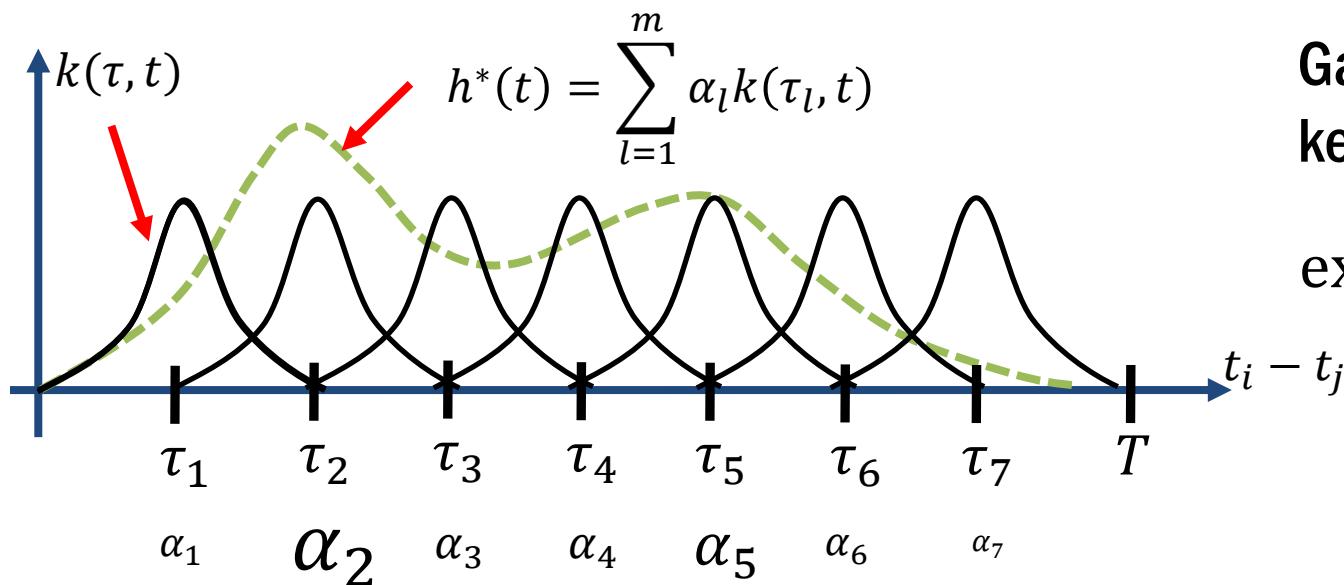

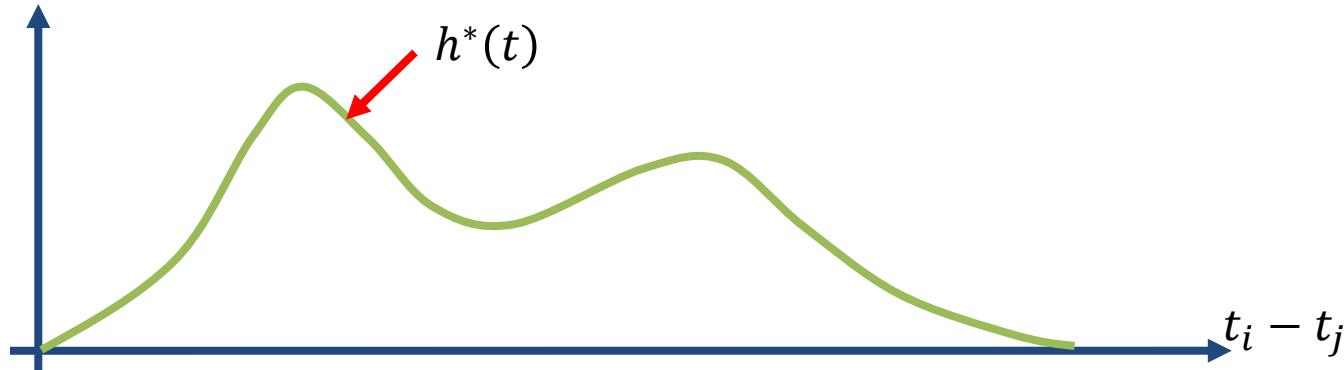

Intensity independent of history

$$h^*(t) = g(t)$$

# Nonparametric form of $h^*(t)$

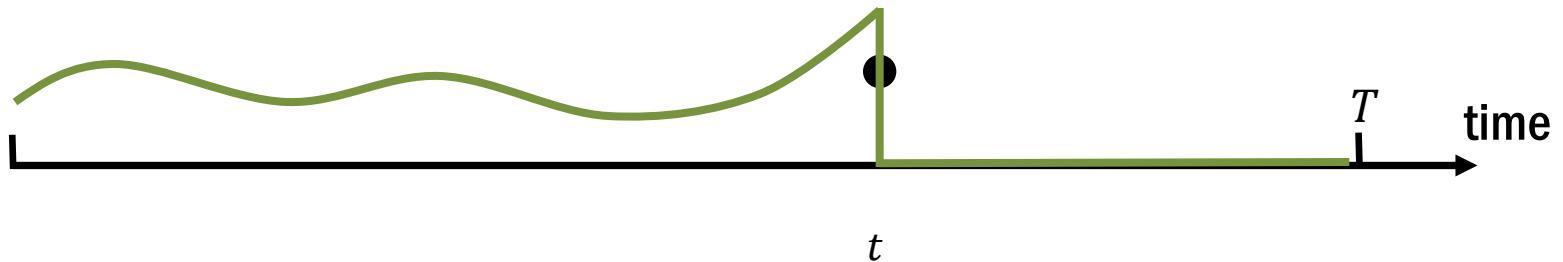

Let  $h^*(t)$  be positive combination of basis functions

**Gaussian RBF kernel  $k(\tau, t)$ :**  
$$\exp\left(-\frac{\|\tau - t\|^2}{2\sigma^2}\right)$$

# Terminating process

Limited number of occurrence

$$h^*(t) = (1 - N(t))g^*(t)$$

# Self-exciting or Hawkes process

Clustered occurrence

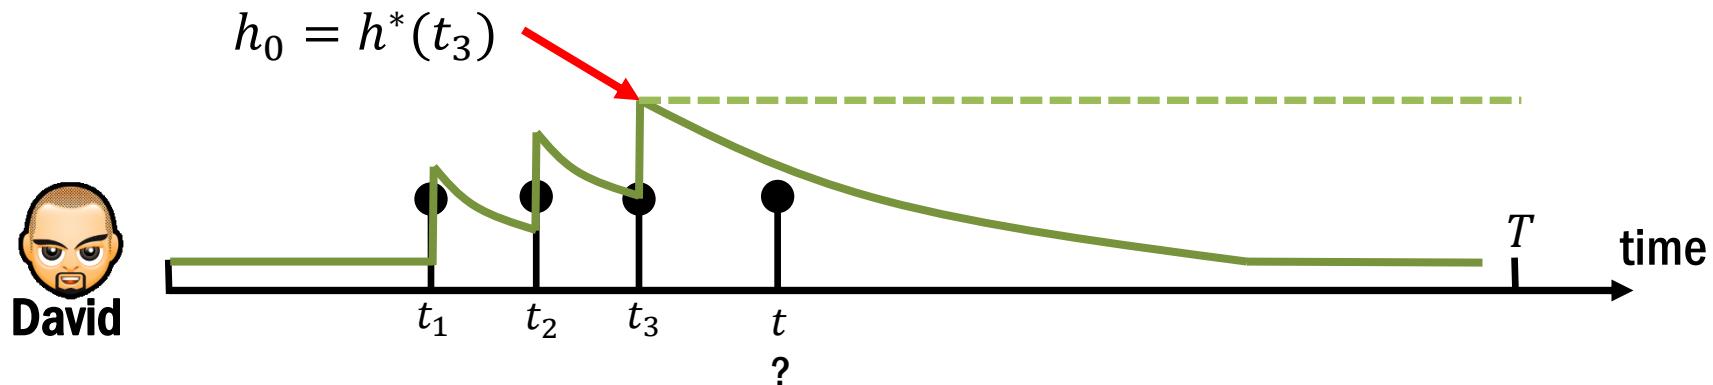

$$h^*(t) = \mu + \alpha \sum_{t_i \in \mathcal{H}_t} \exp(-|t - t_i|)$$

$$= \mu + \alpha \exp(-|t|) \star dN(t)$$

Triggering  
kernel

# How to sample from intensity?

Thinning procedure (similar to rejection sampling)

$$h^*(t) = \mu + \alpha \sum_{t_i \in \mathcal{H}_t} \exp(-|t - t_i|)$$

Sample  $t$  from homogeneous Poisson process with intensity  $h_0$

$$t \sim -\frac{1}{h_0} \ln U[0,1]$$

Keep the sample with probability  $h^*(t)/h_0$

# **Dynamic Processes over Information Networks**

## **Representation, Modeling, Learning and Inference**

**Representation:**  
**Superposition**

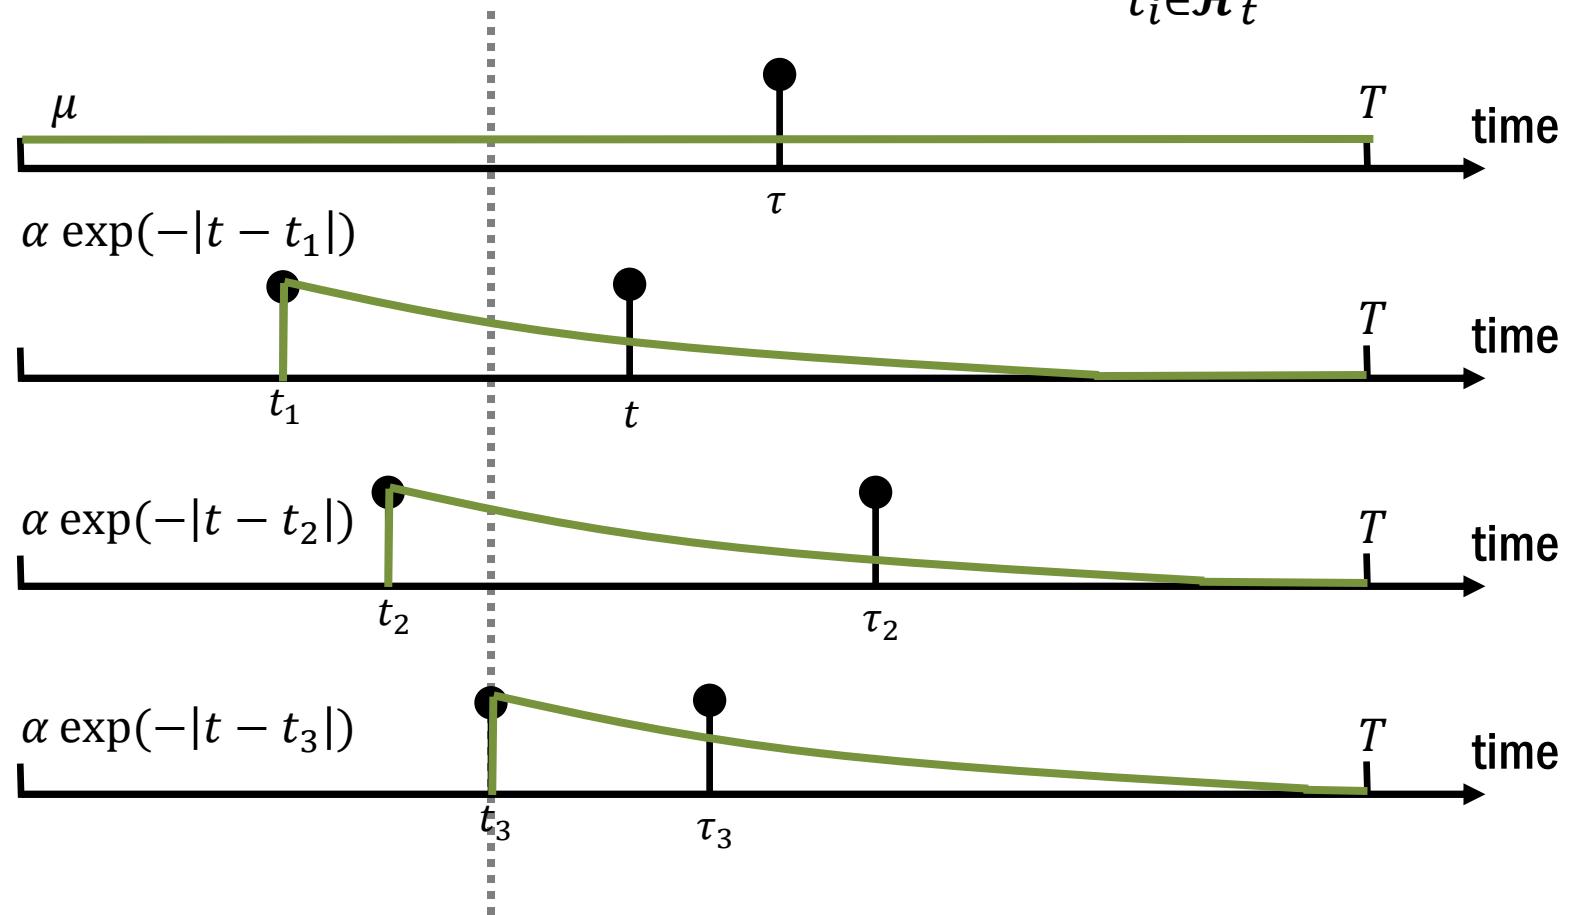

# Supposition of processes

Sample each intensity + take minimum = Additive intensity

$$t = \min\{\tau, \tau_1, \tau_2, \tau_3\} \quad \rightarrow \quad h^*(t) = \mu + \alpha \sum_{t_i \in \mathcal{H}_t} \exp(-|t - t_i|)$$

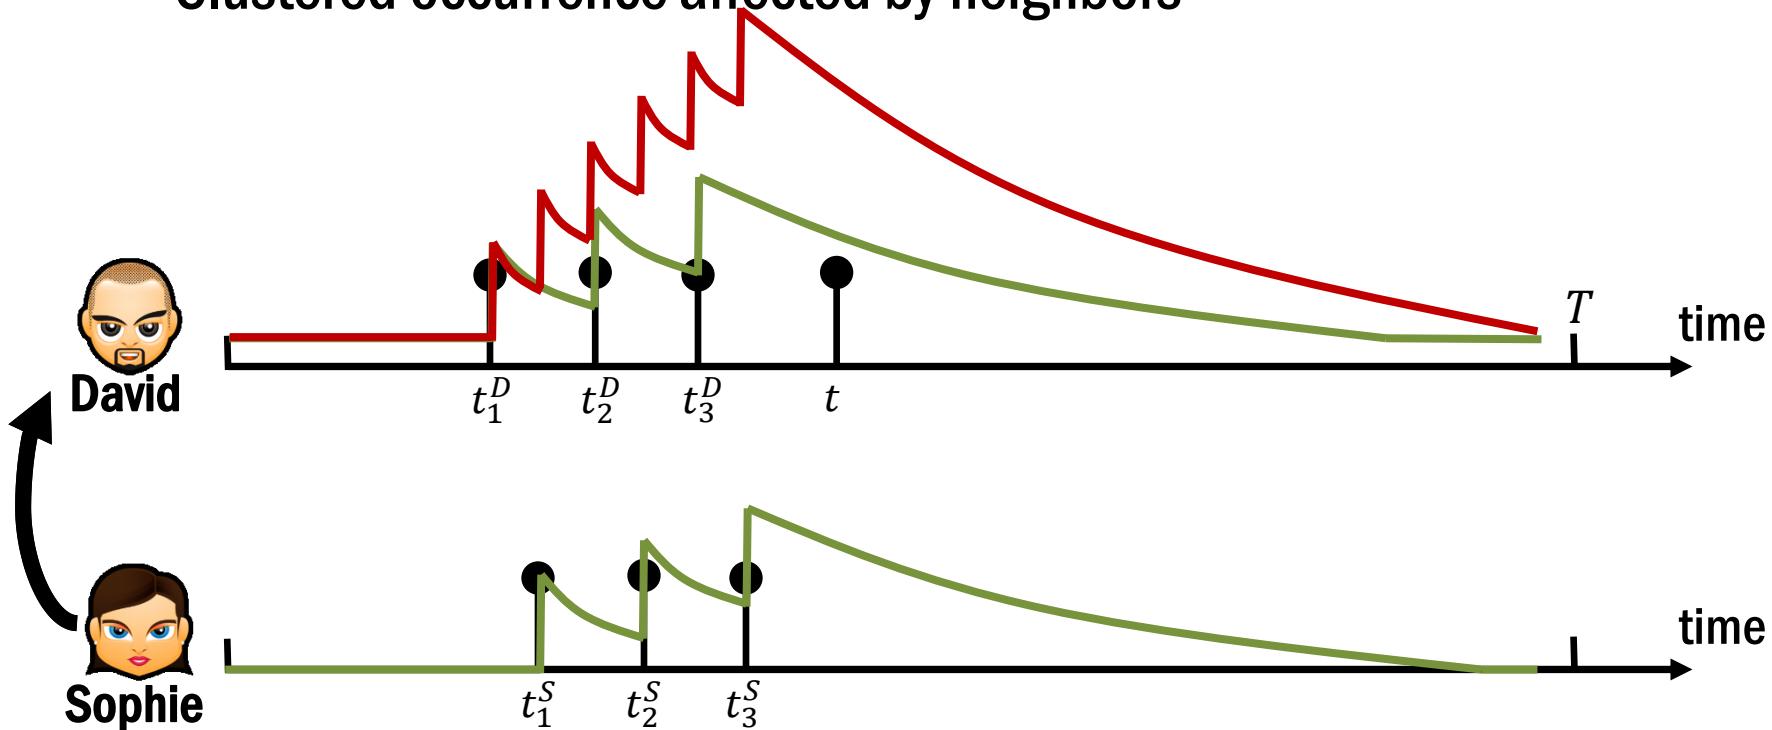

David

# Mutually-exciting process

Clustered occurrence affected by neighbors

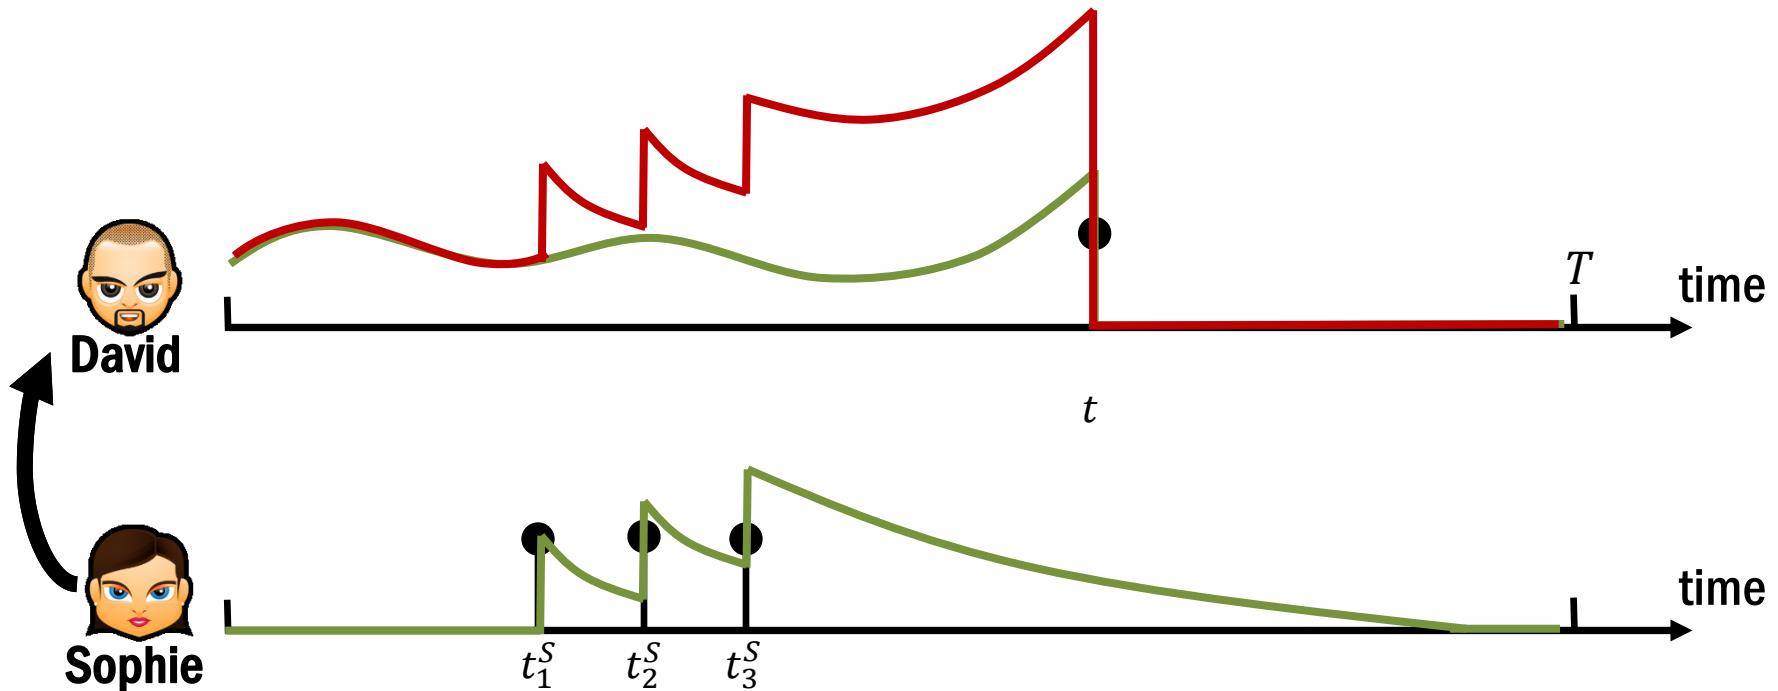

$$h^{D*}(t) = \mu + \alpha^D \sum_{t_i^D \in \mathcal{H}_t^D} \exp(-|t - t_i^D|)$$

$$+ \alpha^{DS} \sum_{t_i^S \in \mathcal{H}_t^S} \exp(-|t - t_i^S|)$$

# Mutually-exciting terminating process

Limited number of occurrence affected by neighbors

$$h^{D*}(t) = (1 - N^D(t)) \left( g^*(t) + \alpha^{DS} \sum_{t_i^S \in \mathcal{H}_t^S} \exp(-|t - t_i^S|) \right)$$

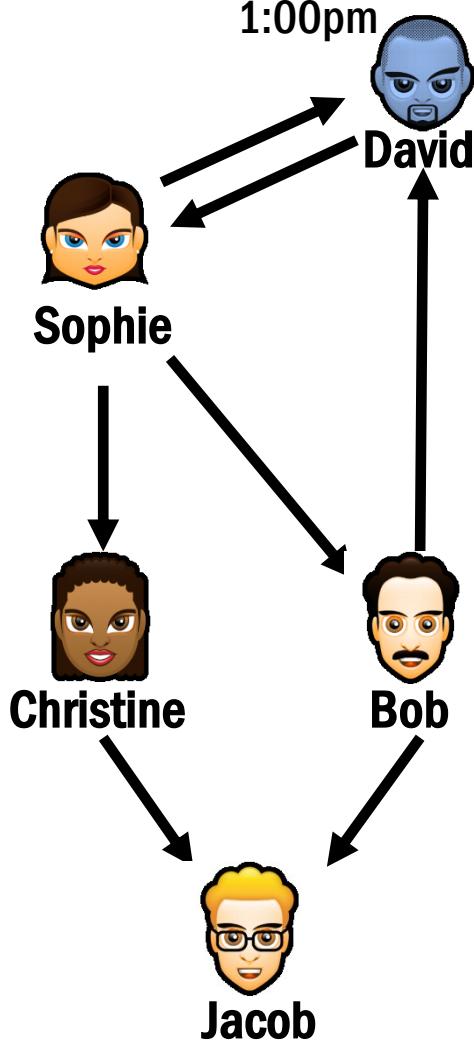

# **Dynamic Processes over Information Networks**

## **Representation, Modeling, Learning and Inference**

**Modeling:**  
**Idea Adoption**

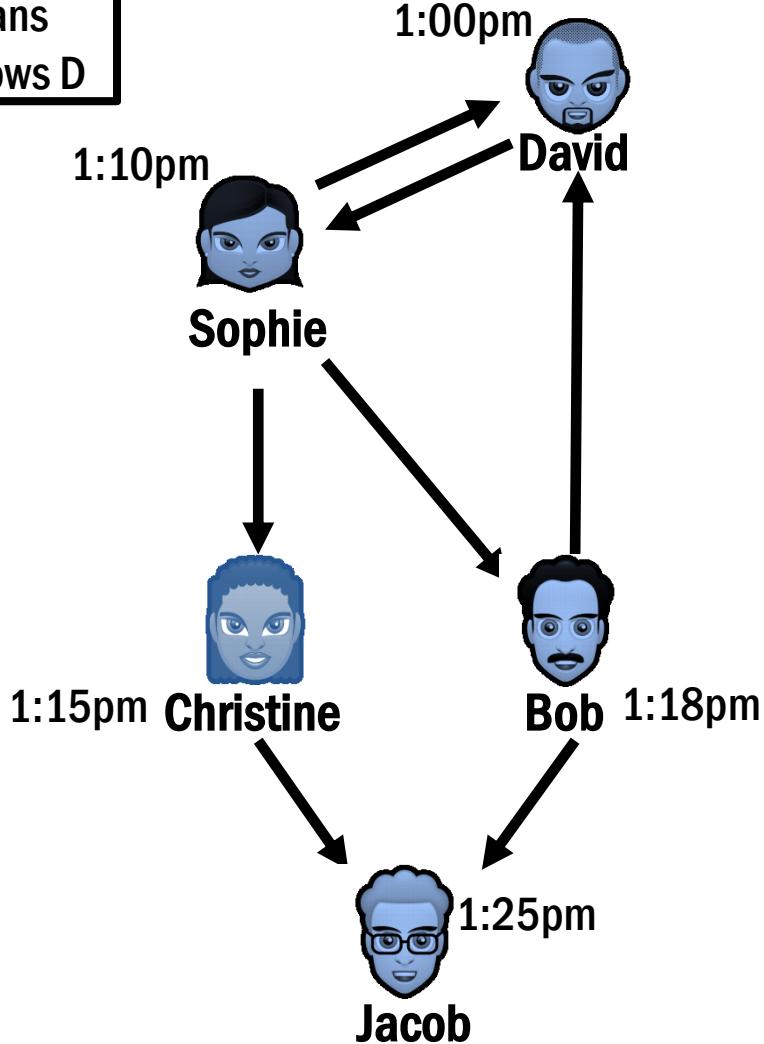

# idea adoption/disease spread/viral marketing

D → S  
means  
S follows D

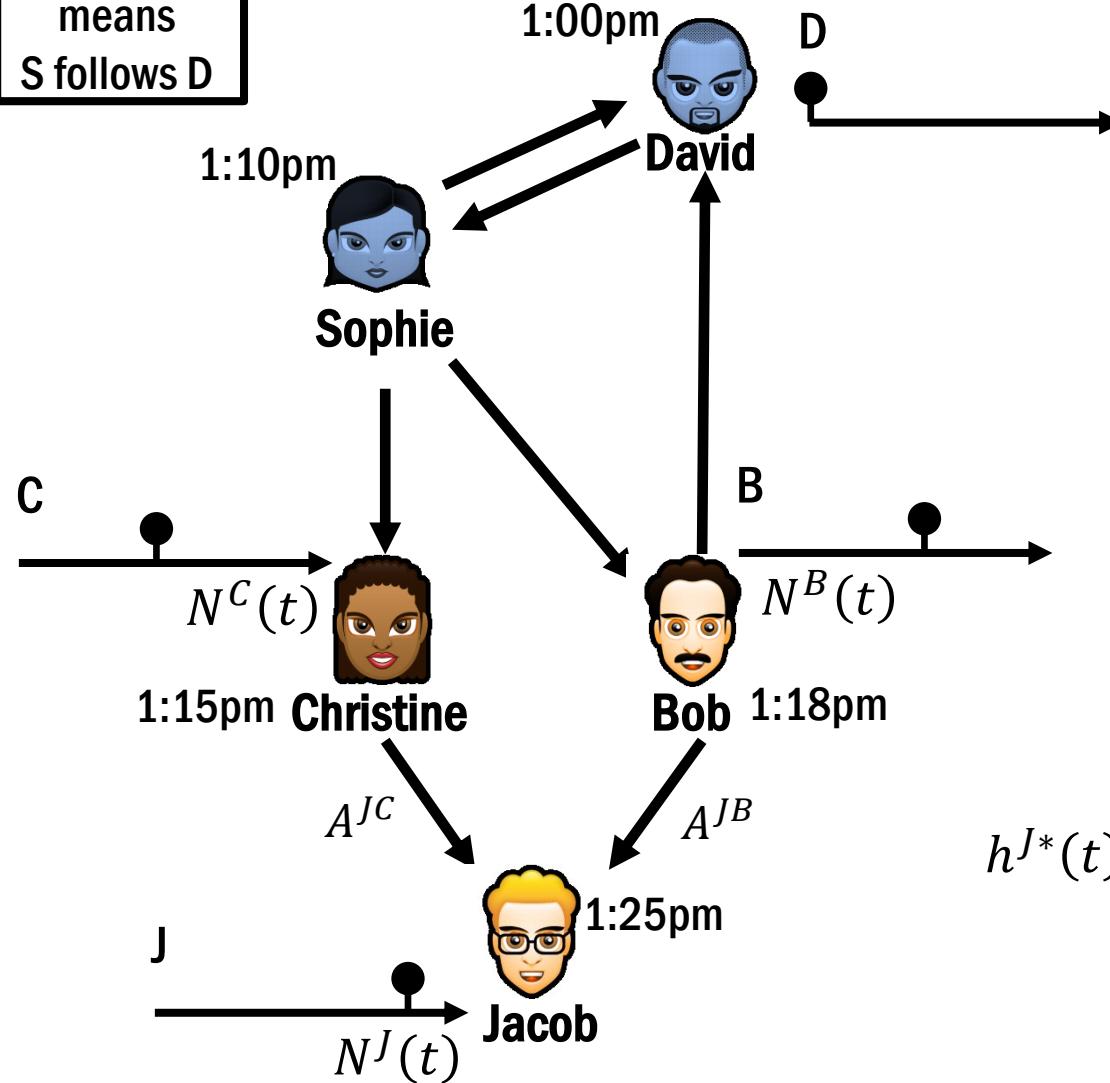

# idea adoption/disease spread/viral marketing

D → S  
means  
S follows D

# Scenario I: idea adoption

D → S  
means  
S follows D

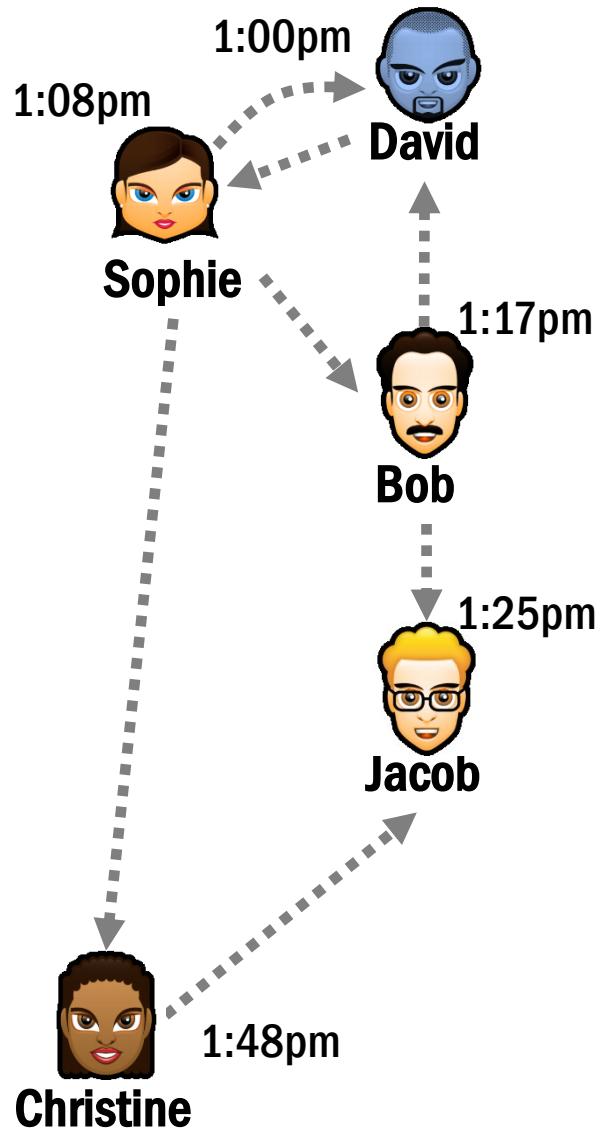

D is source  
 $N^D(t) = 1$

Terminating process  
adopt product only once

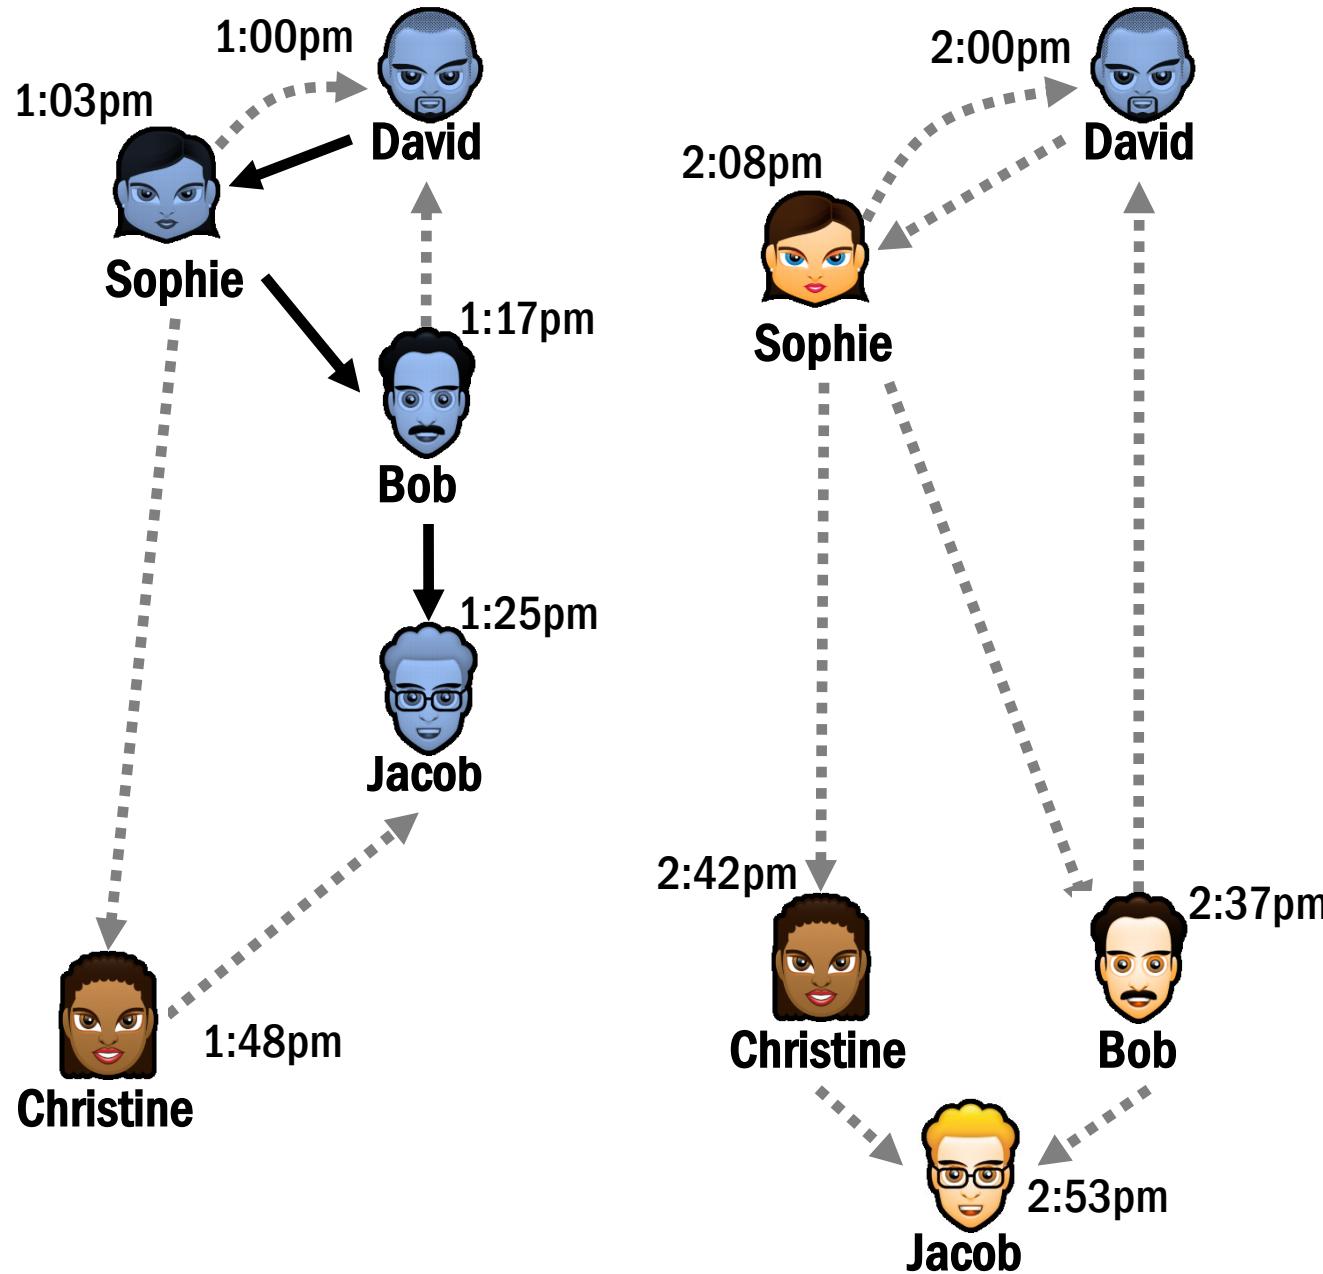

Not yet adopted      Followee adopted

$$h^{J*}(t) = A^{JB}(t) (1 - N^J(t)) N^B(t) + A^{JC}(t) (1 - N^J(t)) N^C(t)$$

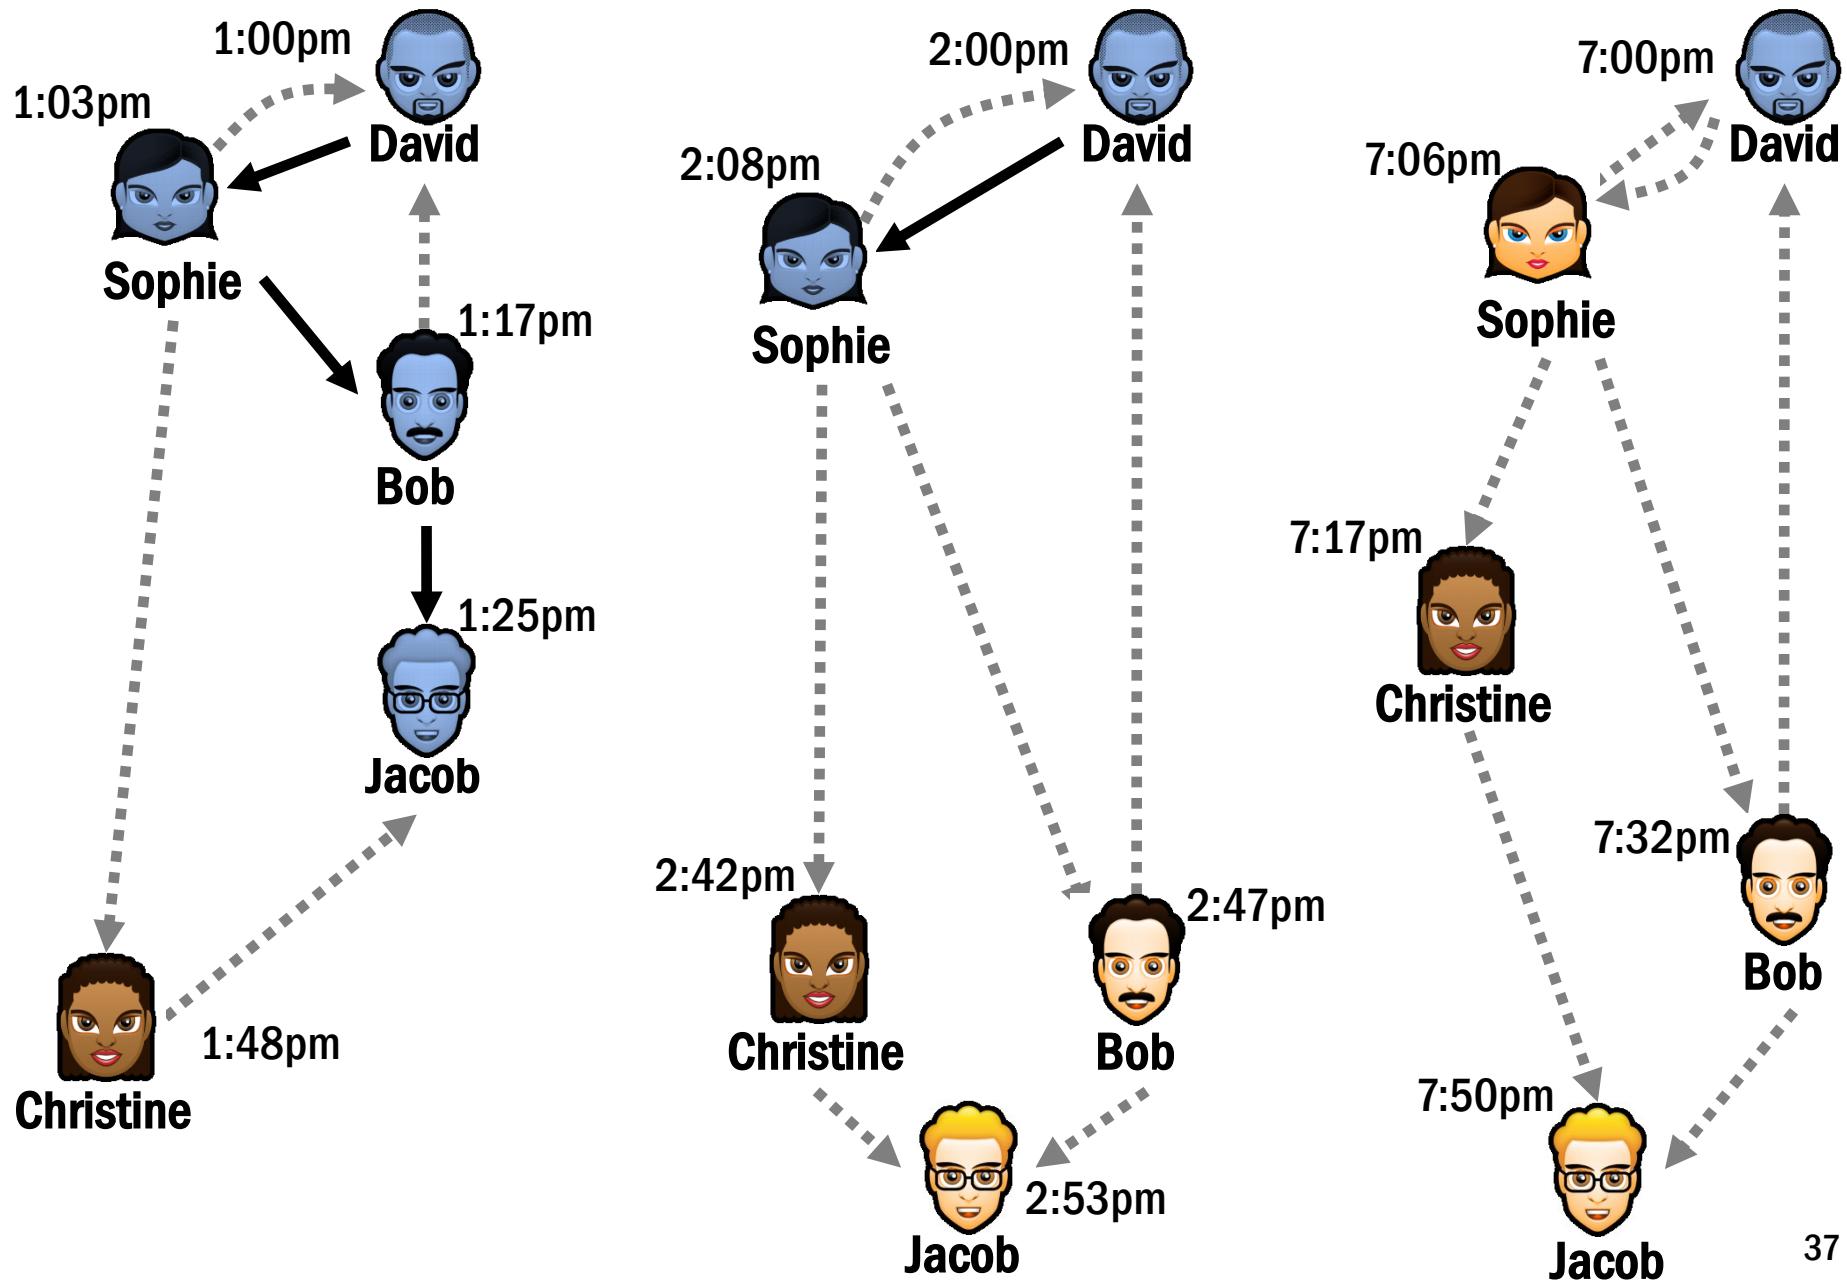

# Cascades from D in 30 mins

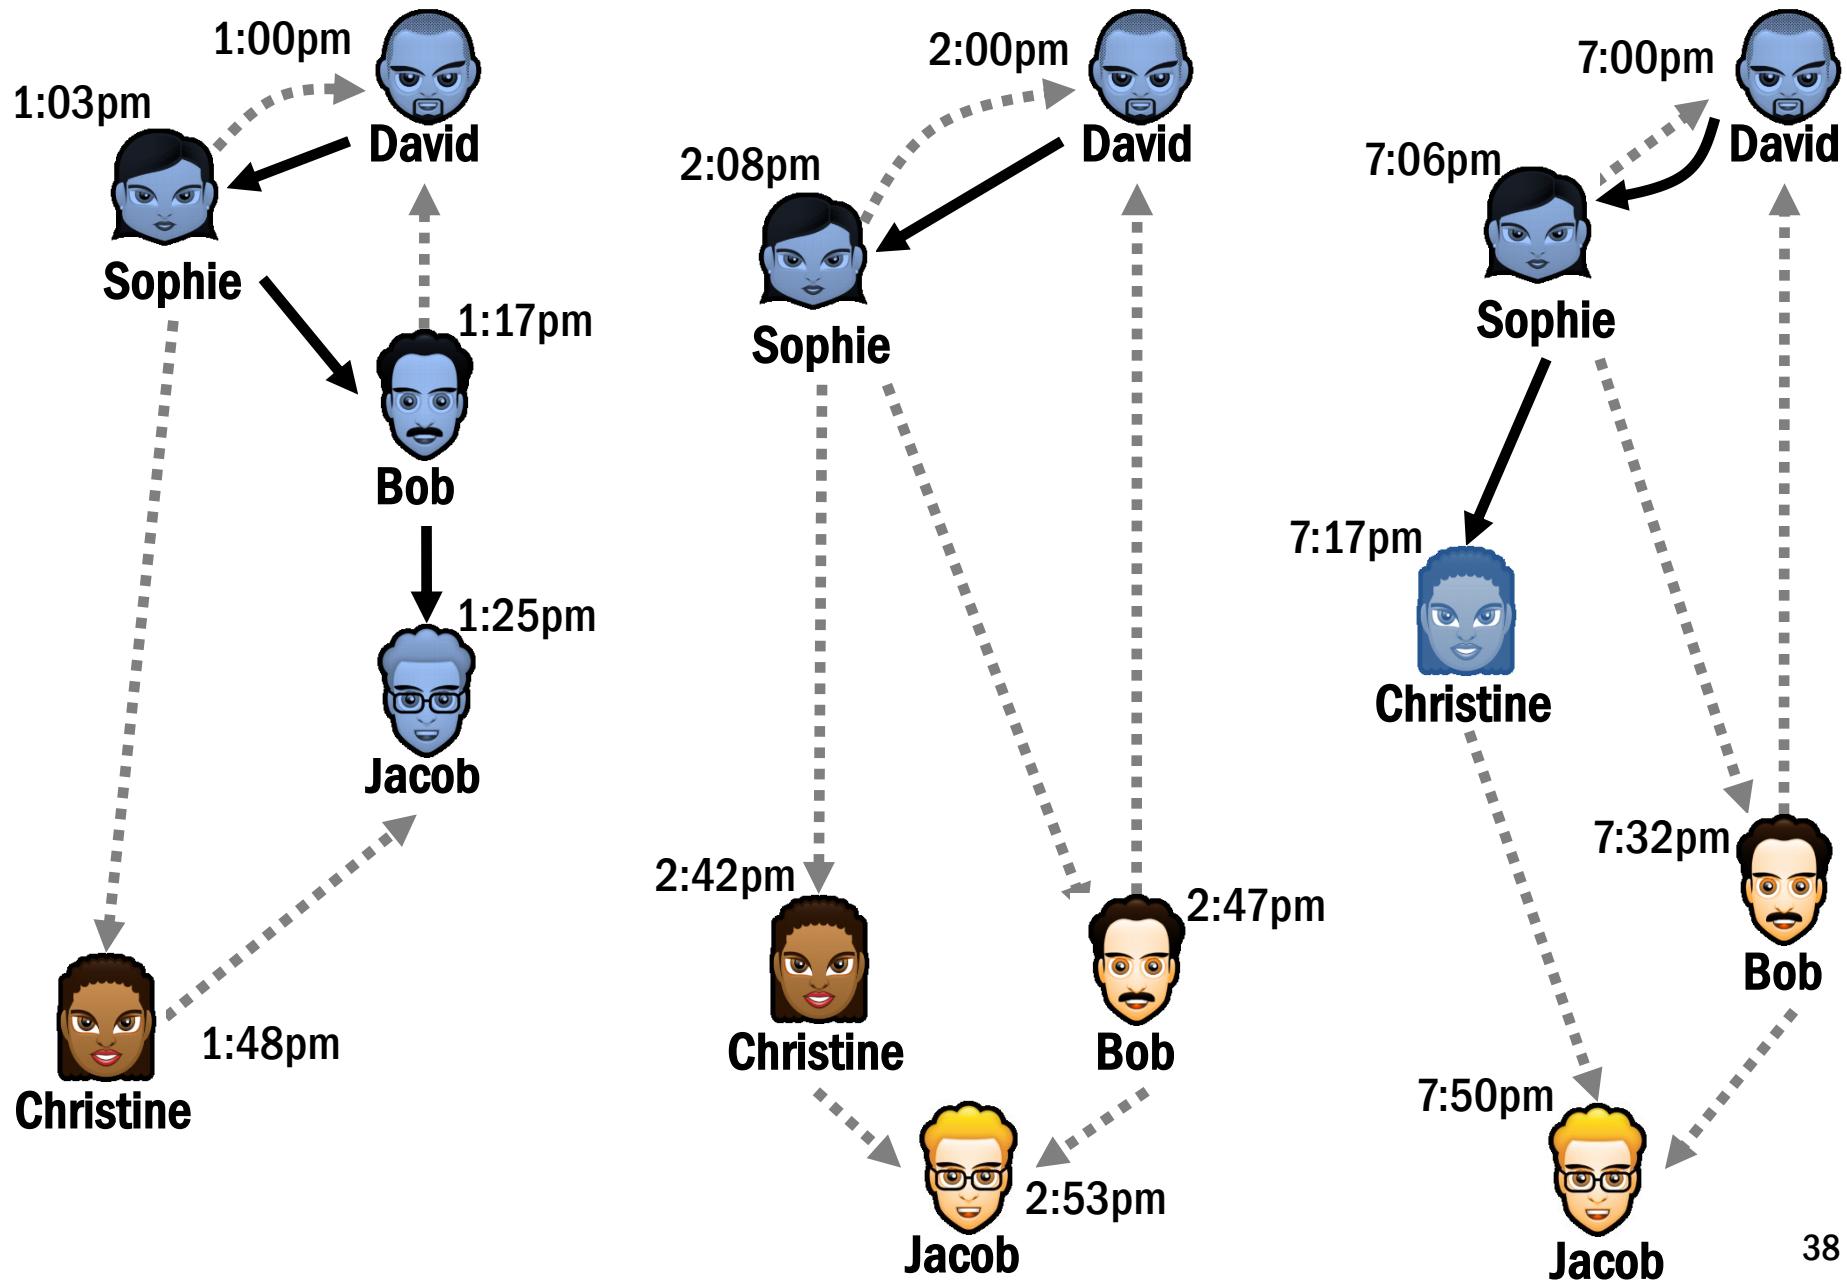

# Cascades from D in 30 mins

# Parametrization of idea adoption model

D → S  
means  
S follows D

Parametrization

$$w = \begin{pmatrix} A^{JD} \\ A^{JS} \\ A^{JB} \\ A^{JC} \end{pmatrix}$$

Terminating process  
adopt product only once

Not yet adopted      Followee adopted

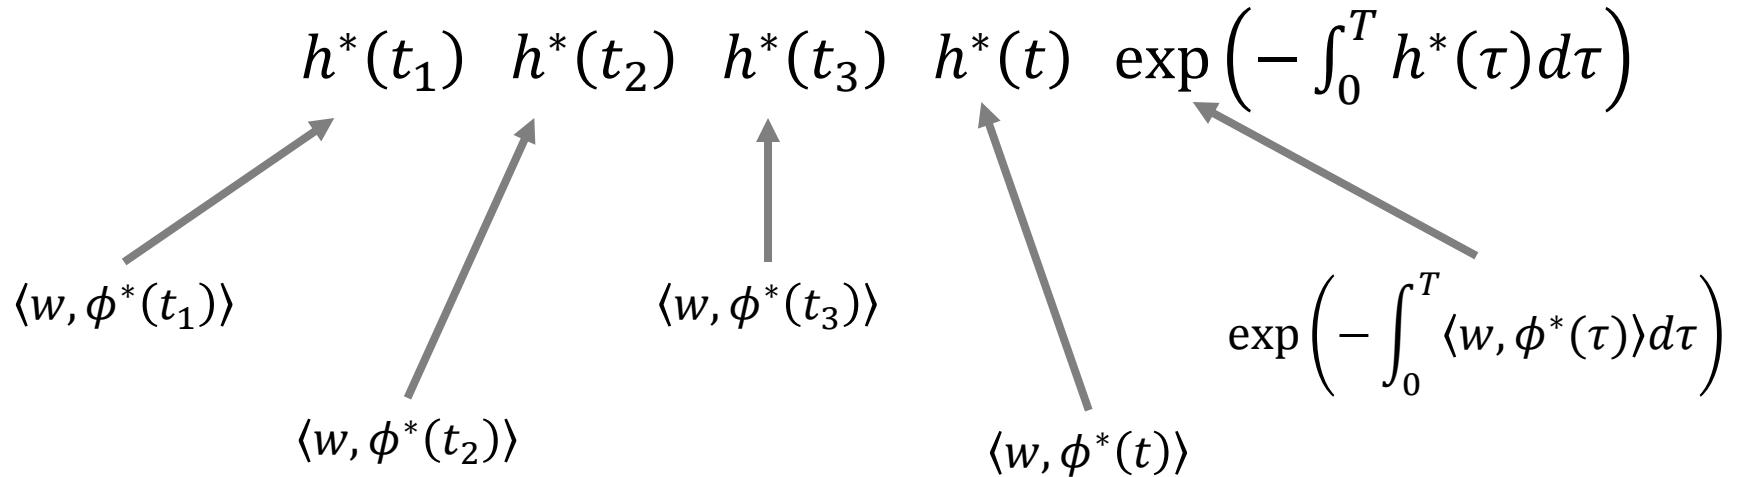

$$h^{J*}(t) = A^{JB} (1 - N^J(t)) N^B(t) + A^{JC} (1 - N^J(t)) N^C(t)$$

# $\ell_1$ Regularized log-likelihood

$$L(w) + \lambda \|w\|_1 = \sum_{i=1}^m \log \langle w, \phi^*(t_i) \rangle - \langle w, \Psi^*(T) \rangle - \lambda \|w\|_1$$

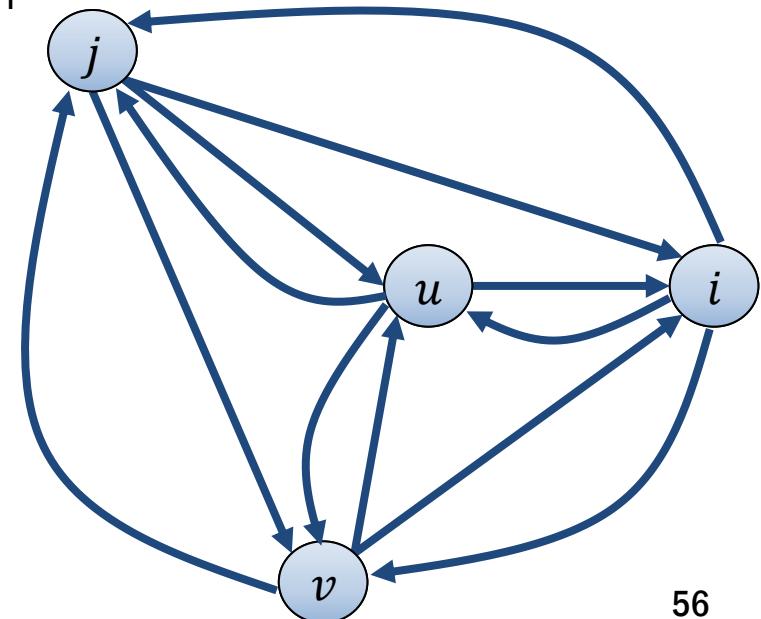

Likelihood:

# Soft-thresholding algorithm

$\ell_1$ -regularized likelihood estimation problem. Solve one such problem for each node.

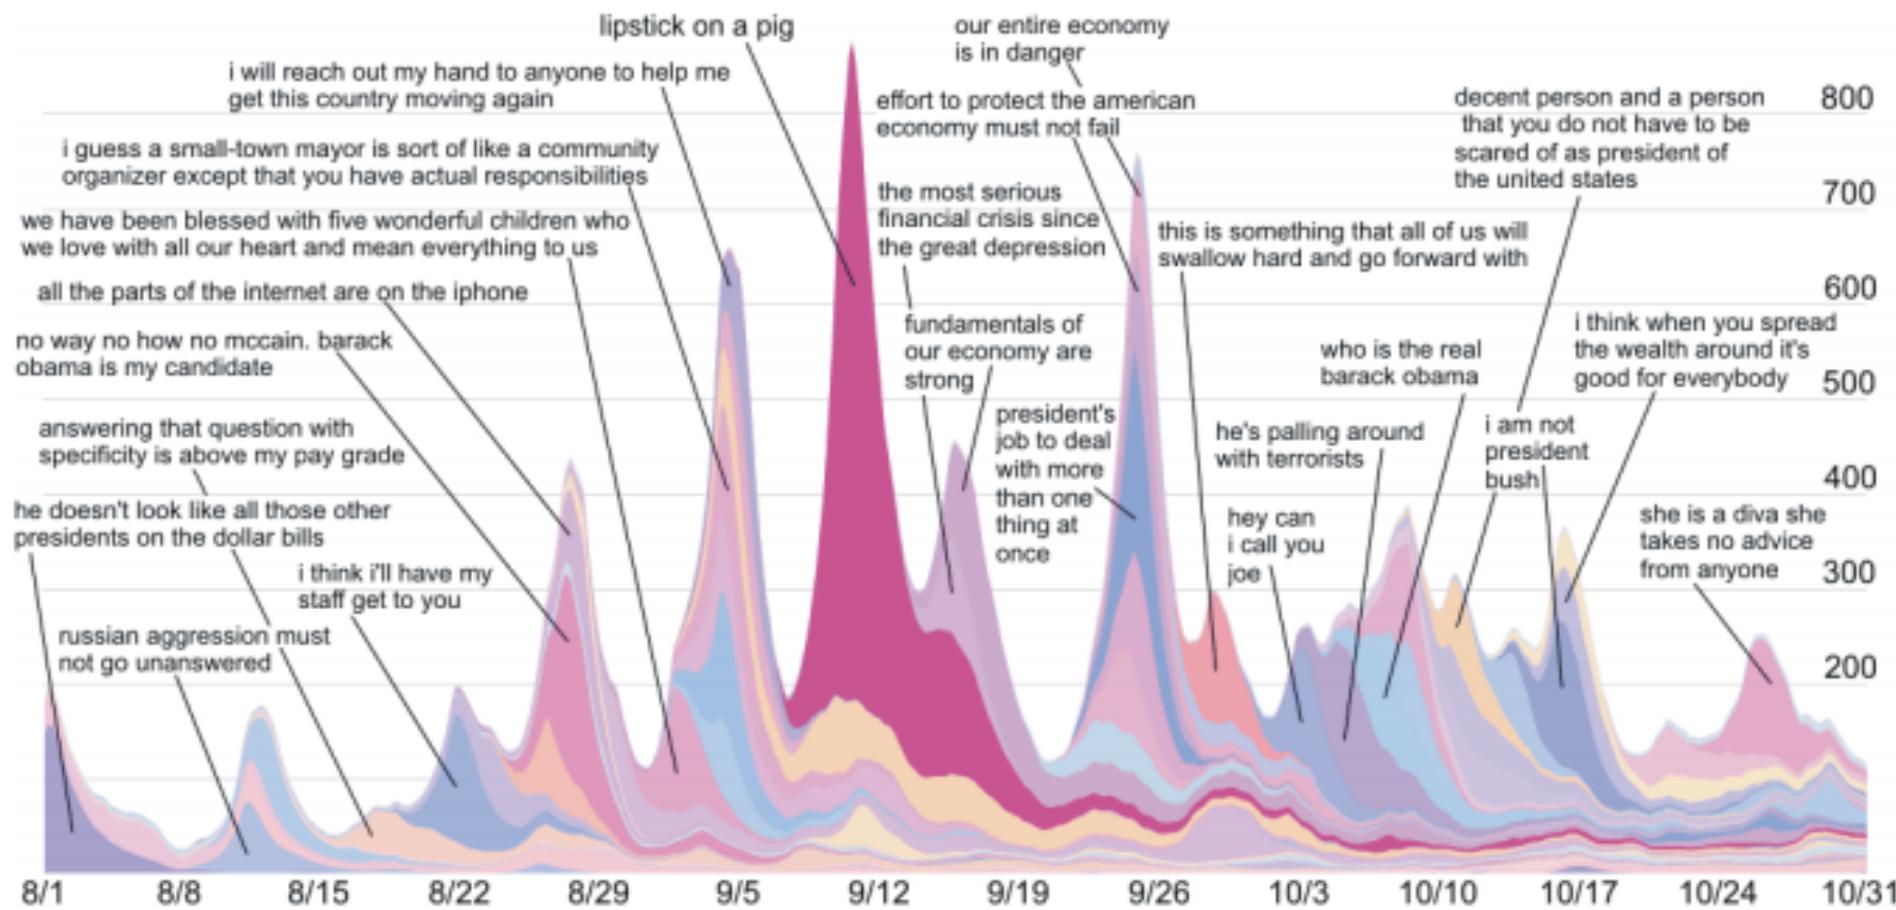

- Set learning rate  $\beta$
- $k = 0$
- Initialize  $w$
- While  $k \leq K$ , do
  - $w^{k+1} = (w^k - \beta \cdot \nabla_w L(w^k) - \lambda \cdot \beta)_+$
  - $k = k + 1$
- End while

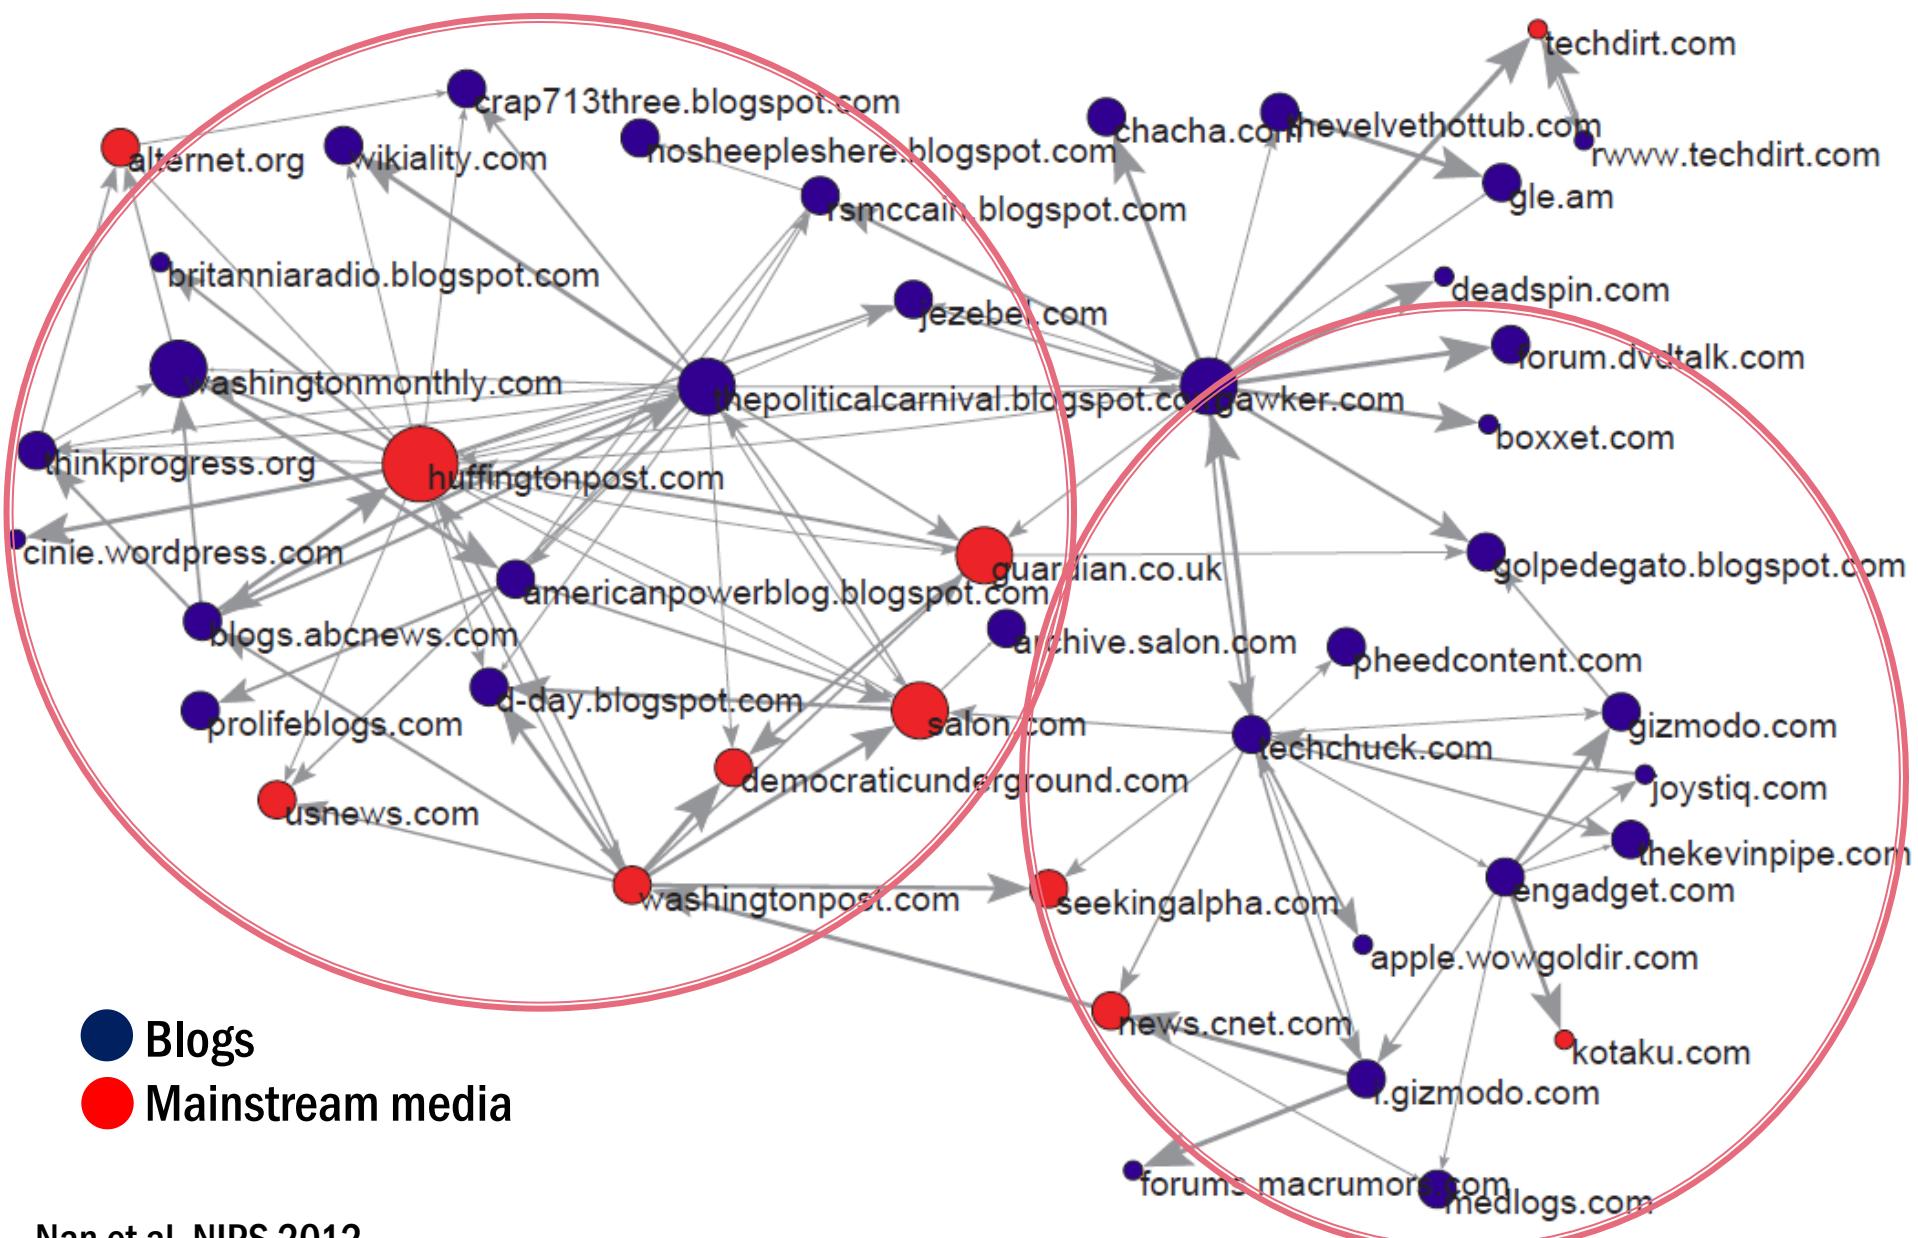

# Statistical guarantees

- Recovery conditions:
  - Eigenvalue of the Hessian,  $Q = \nabla_w^2 L$ , is bounded  $[C_{min}, C_{max}]$
  - Gradient is upper bounded,  $\|\nabla_w L\|_\infty \leq C_1$
  - Hazard is lower bounded,  $\min w_j \geq C_2$
  - Incoherence condition:  $\|Q_{S^c S} (Q_{SS})^{-1}\|_\infty \leq 1 - \varepsilon$ 
    - network structure
    - parameter value
    - observation window
    - source node distribution
- Given  $n > C_3 \cdot d^3 \log p$  cascades, set regularization parameter  $\lambda \geq C_4 \cdot \frac{2-\varepsilon}{\varepsilon} \sqrt{\frac{\log p}{n}}$ , the network structure can be recovered with probability at least  $1 - 2 \exp(-C'' \lambda^2 n)$

## A C++ Multivariate Point Process Package

# Features

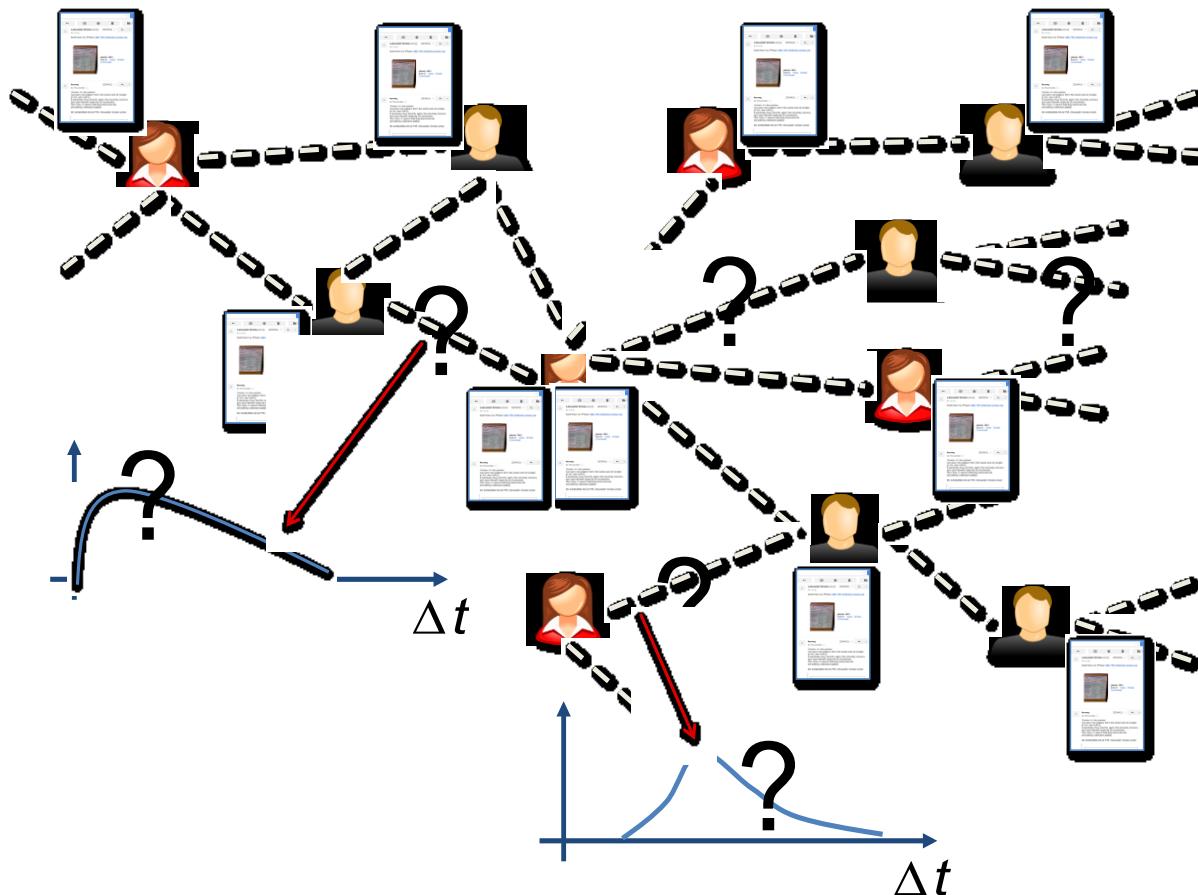

- Learning sparse interdependency structure of continuous-time information diffusions
- Scalable continuous-time influence estimation and maximization
- Learning multivariate Hawkes processes with different structural constraints, like: sparse, low-rank, customized triggering kernels
- Learning low-rank Hawkes processes for time-sensitive recommendations
- Efficient simulation of standard multivariate Hawkes processes
- Learning multivariate self-correcting processes
- Simulation of customized general temporal point processes
- Basic residual analysis and model checking of customized temporal point processes
- Visualization of triggering kernels, intensity functions, and simulated events

# Overview

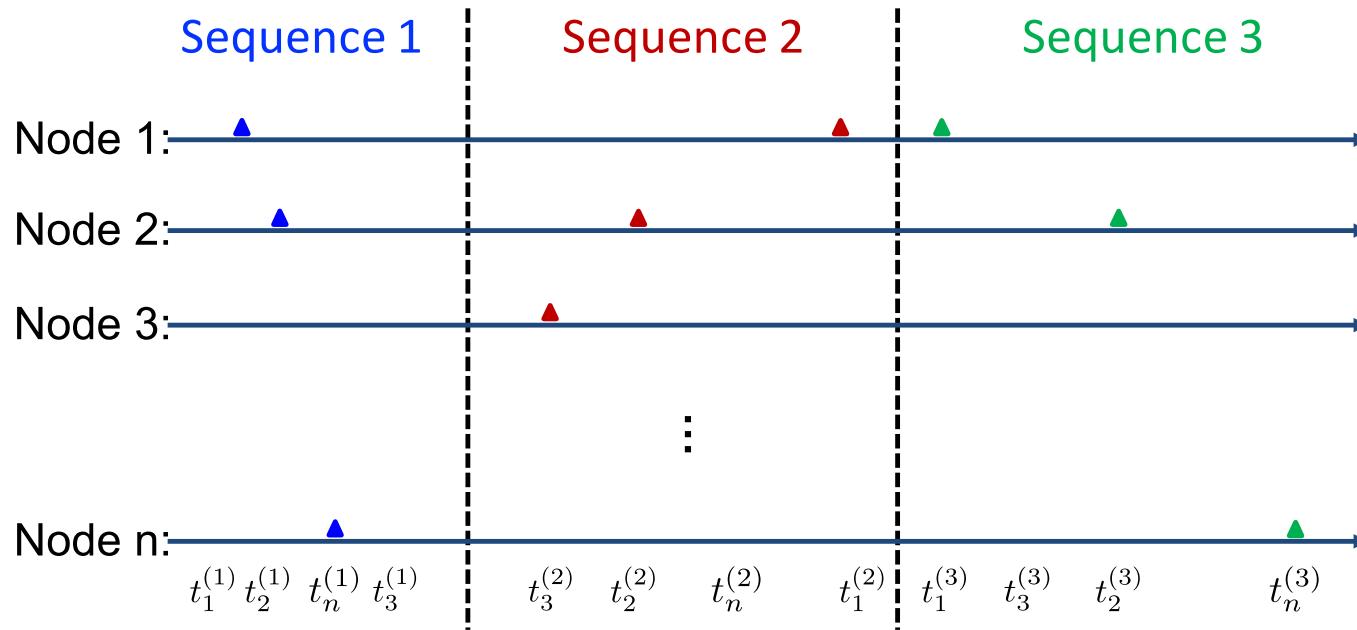

<https://github.com/dunan/MultiVariatePointProcess>

# Demo: learning network structure

# Input: sequences of infection times

node1, time1, node2, time2, node3, time3, .....

Sequence 1 1,0, 3,0.280236, 2,2.02846, 5,2.80793, .....

# Demo: influence maximization

[https://github.com/dunan/MultiVariatePointProcess/blob/master/example/influence\\_maximization.cc](https://github.com/dunan/MultiVariatePointProcess/blob/master/example/influence_maximization.cc)

# Load diffusion networks

- For the demo, we assume pairwise Weibull distribution

$$f_{ji}(\Delta t; \alpha, \beta) = \frac{\beta}{\alpha} \left( \frac{\Delta t}{\alpha} \right)^{\beta-1} e^{-(\Delta t/\alpha)^\beta}$$

The diagram shows two red arrows originating from the labels "scale parameter" and "shape parameter". The arrow from "scale parameter" points to the parameter  $\alpha$  in the formula. The arrow from "shape parameter" points to the parameter  $\beta$  in the formula.

- For each edge, we have:

node  $j$ , node  $i$ ,  $\beta_{ji}$ ,  $\alpha_{ji}$

# Load diffusion networks

```
// suppose 1024 nodes
2 unsigned N = 1024;

4 // load network with edge reversed
Graph G("data/std_weibull_DAG_core-1024-1-network", N, true);
6 // load the original network for comparing with the monte-carlo
  simulations
Graph G1("data/std_weibull_DAG_core-1024-1-network", N, false);

8 // use 5000 sampled networks, each of which has 5 sets of node labels
10 unsigned num_samples = 5000, num_labels = 5;

12 // initialize influence estimation
ConTinEst continest(&G, &G1, num_samples, num_labels);
```

# Influence estimation

```
1 std::cout << "Get all least-label lists : " << num_samples << " sets of
2   transmission times; " << num_labels << " sets of random labels; ";
3
4 // calculate least-neighbor lists for each node
5 continest.GetLeastElementLists();
6
7 std::cout << "done" << std::endl << std::endl;
8
9 // use 10000 monte carlo simulations for comparison
10 unsigned C = 10000;
11
12 // increase observation window from 1 to 10
13 for(unsigned T = 1; T <= 10; ++ T)
